The Research and Technology Organization (RTO) of NATO

RTO is the single focus in NATO for Defence Research and Technology activities. Its mission is to conduct and promote cooperative research and information exchange. The objective is to support the development and effective use of national defence research and technology and to meet the military needs of the Alliance, to maintain a technological lead, and to provide advice to NATO and national decision makers. The RTO performs its mission with the support of an extensive network of national experts. It also ensures effective coordination with other NATO bodies involved in R&T activities.

RTO reports both to the Military Committee of NATO and to the Conference of National Armament Directors. It comprises a Research and Technology Board (RTB) as the highest level of national representation and the Research and Technology Agency (RTA), a dedicated staff with its headquarters in Neuilly, near Paris, France. In order to facilitate contacts with the military users and other NATO activities, a small part of the RTA staff is located in NATO Headquarters in Brussels. The Brussels staff also coordinates RTO's cooperation with nations in Middle and Eastern Europe, to which RTO attaches particular importance especially as working together in the field of research is one of the more promising areas of initial cooperation.

The total spectrum of R&T activities is covered by 7 Panels, dealing with:

- SAS Studies, Analysis and Simulation
- SCI Systems Concepts and Integration
- SET Sensors and Electronics Technology
- IST Information Systems Technology
- AVT Applied Vehicle Technology
- HFM Human Factors and Medicine
- MSG Modelling and Simulation

These Panels are made up of national representatives as well as generally recognised 'world class' scientists. The Panels also provide a communication link to military users and other NATO bodies. RTO's scientific and technological work is carried out by Technical Teams, created for specific activities and with a specific duration. Such Technical Teams can organise workshops, symposia, field trials, lecture series and training courses. An important function of these Technical Teams is to ensure the continuity of the expert networks.

RTO builds upon earlier cooperation in defence research and technology as set-up under the Advisory Group for Aerospace Research and Development (AGARD) and the Defence Research Group (DRG). AGARD and the DRG share common roots in that they were both established at the initiative of Dr Theodore von Kármán, a leading aerospace scientist, who early on recognised the importance of scientific support for the Allied Armed Forces. RTO is capitalising on these common roots in order to provide the Alliance and the NATO nations with a strong scientific and technological basis that will guarantee a solid base for the future.

Technologies for Future Precision Strike Missile Systems

(RTO EN-13)

Executive Summary

This report documents the results of NATO Research and Technology Organization (RTO) lecture series number 221, entitled "Technologies for Future Precision Strike Missile Systems." The primary purpose of the lecture series was the disseminating of state-of-the-art scientific and technical knowledge among a wide audience. The lecture series director and two other speakers provided lecturers.

Emerging technologies for precision strike missile systems that were addressed in the lecture series included:

- Missile aeromechanics technologies. Assessments included hypersonic airframes, low cost/high temperature structure, and ramjet propulsion.
- Guidance & control technologies. Assessments included precision navigation using light weight/low cost GPS/INS and optimal guidance laws.
- Seeker technologies. Assessments included active and passive infrared and millimeter wave seekers.
- Missile design technologies. Assessments included computer programs and electronic spreadsheets for conceptual design.
- Missile/aircraft integration technologies. Assessments included high firepower weapon concepts, reduced observables, and insensitive munitions.
- Simulation/validation technologies. Assessments included hardware-in-the-loop and design validation.
- Automatic target recognition. Assessments included robust algorithms and hardware/algorithm optimization.

The material in this publication was assembled to support a Lecture Series under the sponsorship of the Systems Concepts and Integration Panel (SCI) and the Consultant and Exchange Programme of RTO presented on 23-24 March in Atlanta, USA, on 3-4 April, 2000 in Turin, Italy, and on 6-7 April, 2000 in Ankara, Turkey.

les Technologies des futurs systèmes de missiles pour frappe de précision

(RTO EN-13)

Synthèse

Ce rapport présente les résultats du Cycle de conférences No. 221 sur « Les technologies des futurs systèmes de missiles pour frappe de précision » organisé par l'Organisation pour la recherche et la technologie de l'OTAN (RTO). Ce cycle de conférences a eu pour objectif principal la diffusion, auprès d'un public travaillant dans un grand éventail de domaines, de connaissances scientifiques et techniques de pointe. Les communications ont été fournies par le Directeur du cycle de conférences et deux autres conférenciers.

Les technologies naissantes suivantes, relatives aux systèmes de missiles pour frappe de précision, ont été abordées

- les technologies de l'aéromécanique des missiles avec une évaluation des cellules hypersoniques, des structures à coût modéré, résistant aux hautes températures, et de la propulsion par statoréacteur.
- les technologies du guidage et du pilotage avec une évaluation de la navigation de précision à l'aide d'équipements GPS/INS légers et à coût modique et de lois de guidage optimisées.
- les technologies des autodirecteurs, avec une évaluation des autodirecteurs actifs et passifs à ondes millimétriques et infrarouge.
- les technologies de l'aéromécanique des missiles avec une évaluation des programmes informatiques d'étude de définition et des tableurs.
- les technologies d'intégration missile/aéronef avec une évaluation des concepts des armements à grande puissance de feu, la furtivité et les munitions à risques atténués.
- les technologies de simulation/validation avec une évaluation du matériel dans la boucle et de la validation de la conception.
- les technologies de la reconnaissance automatique de la cible avec une évaluation de l'optimisation du matériel par rapport aux algorithmes et des algorithmes robustes.

Cette publication a été rédigée pour servir de support de cours pour le Cycle de conférences 221, organisé par la Commission RTO sur les (SCI) dans le cadre du programme des consultants et des échanges de la RTO du 23-24 mars 2000, à Atlanta, Etats-Unis et du 3-4 avril 2000 à Turin, Italie, et du 6-7 avril 2000 à Ankara, Turquie.

Abstract/Executive Summary

This report documents the results of NATO Research and Technology Organization (RTO) lecture series number 221, entitled "Technologies for Future Precision Strike Missile Systems." The lecture series was conducted under the RTO Consultant and Exchange (C&E) Program as a two-day educational event, first held March 23-24, 2000 in Atlanta Georgia, at the Georgia Institute of Technology. Following the lectures at Georgia Tech, the lectures were held April 3-4 in Turin, Italy and April 6-7 in Ankara, Turkey.

The primary purpose of the lecture series was the disseminating of state-of-the-art scientific and technical knowledge among a wide audience. The lecture series director and three other speakers provided lectures.

Emerging technologies for precision strike missile systems that were addressed in the lecture series included:

Missile aeromechanics technologies. Assessments included hypersonic airframes, low cost/high temperature structure, and ramjet propulsion.

Guidance & control technologies. An overview of existing guidance and control was given. Assessments included precision navigation using light weight/low cost GPS/INS and optimal guidance laws.

Seeker technologies. Assessments included active and passive imaging infrared and radar seekers.

Missile design technologies. An overview of the missile design process was given. Assessments included computer programs and electronic spreadsheets for conceptual design and missile design criteria.

Missile/aircraft integration technologies. Assessments included high firepower weapon concepts, reduced observables, and insensitive munitions.

Simulation/validation technologies. Assessments included hardware-in-the-loop and design validation.

Automatic target recognition. Assessments included robust algorithms and hardware/algorithm optimization.

Introduction

The last decade has seen increased usage of precision strike missile systems for military strike operations. Moreover, precision strike missiles are expected to have an even larger share of military strike operations in the future. A key contributor to the increased effectiveness of precision strike missiles is the advancement in technology. Examples of system effectiveness improvements include improved missile accuracy, lethality, and adverse weather capability. This lecture series provided insight into the enabling technologies and the state-of-the-art for precision strike missile systems.

The technical program for the lectures consisted of two days. The first day included registration, opening ceremony, an introduction/overview, and lectures on missile aeromechanics technology, guidance & control technology, seeker technology, and missile design technology. Day 2 continued the program with lectures on missile/aircraft integration, simulation/validation, and automatic target recognition technologies. Following the lectures, there was a round-table discussion to address questions and comments from the attendees. The lecture series director provided concluding remarks.

The lecture series director was Mr. Eugene Fleeman of the Georgia Institute of Technology. Other speakers were Mr. Erik Berglund of the Swedish Defense Research Establishment, and Mr. William Licata of the Raytheon Company.

Figure 1. Emphasis of This Lecture Series Is on Technologies for Precision Strike Missiles.

Figure 1 summarizes the focus of this lecture series. Primary areas of emphasis were technologies in aerodynamics, propulsion, structures/materials, guidance and control, seeker, missile design, missile/aircraft integration, simulation/validation, and automatic target recognition (ATR). Other areas that were addressed, but with lesser emphasis, included missile cost/logistics, reduced observables, and survivability.

This lecture series recognizes that precision strike missiles are different from other flight vehicles, such as combat aircraft. Precision strike missiles are a technical specialty in their own right. For example, Figure 2 compares precision strike missile characteristics and the current state-of-the-art (SOTA) with that of fighter aircraft. Examples are shown where missiles are driving technology. Also shown are other areas where the missile is not driving technology in comparison with fighter aircraft.

As an example, the lateral and longitudinal acceleration SOTA of missiles exceeds that of combat aircraft. Missile lateral maneuverability of 30+ g's and longitudinal acceleration of 30+ g's have been demonstrated. Notable examples of precision strike missiles with high acceleration and maneuverability include AGM-88 HARM and AGM-114 Hellfire missiles. Missile speed is also usually greater than that of combat aircraft, an example is the AS-17/Kh 31 hypersonic ramjet missile. Another difference is dynamic pressure loading on a missile, which is usually greater than of combat aircraft. An example of a precision strike missile that operates at high dynamic pressure is the ANS ramjet missile. Another difference is the relatively small size and lighter weight of missiles in comparison to combat aircraft, notably the LOCAAS powered submunition. Related to cost, missiles are a throw-away. As a result, they are more cost-driven than combat aircraft.

Precision Strike Missile Characteristics	Example of State-of-the-Art	Comparison With Fighter Aircraft
Acceleration	AGM-88	●
Maneuverability	AGM-114	●
Speed	AS-17 / Kh-31	●
Dynamic pressure	ANS	●
Size	LOCAAS	●
Weight	LOCAAS	●
Production cost	GBU-31	●
Observables	AGM-129	○
Range	AGM-86	-
Kills per use	Apache	-
Target acquisition	LOCAAS	-

● Superior ○ Better ○ Comparable - Inferior

Figure 2. Air-Launched Precision Strike Missiles are Different from Fighter Aircraft.

Development cost is smaller for missiles and the difference in production cost is even more dramatic. An example is the GBU-31 JDAM, with cost on the order of \$10,000, compared to 10's of millions of dollars for typical combat aircraft. Finally, cruise missiles such as AGM-129 are able to achieve low radar cross section without the other design limitations associated with piloted aircraft.

Areas where the combat aircraft have superior capability include range, targets killed per use, and target acquisition. Although the conventional version of the AGM 86 cruise missile (CALCM) has a flight range that can exceed 1,000 nautical miles, combat aircraft have much longer range. In the area of target kill capability, precision strike missiles have become more efficient in recent years, with a single target kill probability approaching one and a capability for multiple target kills. The Apache missile is an example of an efficient precision strike missile. It has high accuracy and is capable of dispensing submunitions, exhibiting high firepower. However the same missiles are load-outs on combat aircraft, and so the enhancement in missiles also enhances the combat aircraft effectiveness and firepower. Finally, although smart, powered submunitions such as LOCAAS have demonstrated a capability for automatic target recognition (ATR), combat aircraft with a human pilot continues to have superior capability for target recognition, discrimination and acquisition. Autonomous target acquisition by missiles is a relatively immature technology that will improve in the future with new technologies such as multi-mode and multi-spectral seekers.

One of the greatest strengths of a precision strike missile is a reduction in the number of aircraft sorties required to destroy a target. A historical example is the Thanh Hoa Bridge in Vietnam. For over six years, a total of 871 aircraft sorties dropped unguided bombs, but failed to close the bridge. However, on 13 May 1972 only four aircraft sorties using laser-guided munitions resulted in direct hits on the supporting

piers, dropping the center span and closing the bridge. Precision strike munitions also reduce aircraft attrition losses and the number of downed/captured pilots. Eleven aircraft were lost using unguided munitions in the 871 sorties mentioned above. No aircraft were lost in the four sorties using precision guided munitions.

Examples of Precision Strike Missiles

Figure 3 shows examples of precision strike missiles, characterized according to the targets they are intended to attack.

In the case of **fixed targets** (which are usually large size and relatively soft), a blast fragmentation or dispensed submunition warhead is usually used. Examples of missiles suitable for fixed surface targets include AGM-154 JSOW, Apache, KEPD-350, BGM-109 Tomahawk, and AGM-142 Have Nap.

Another target category is **radar sites**. Radar sites are also relatively soft, anti-radar homing (ARH) missiles usually use blast fragmentation warheads. Modern ARH missiles include AGM-88 HARM, AS-11 Kilter/Kh-58, ARMAT, AS-12 Kegler/Kh-27, and ALARM.

A third target category is **ship targets**. Ship targets are relatively hard targets and require a kinetic energy

penetrating warhead, followed by blast fragmentation after penetration of the hull. Anti-ship missiles include the MM40 Exocet, AS-34 Kormoran, AS-17 Krypton/Kh-34, Sea Eagle, and SS-N-22 Sunburn/3M80.

A fourth target category is **armor targets**. This includes tanks, armored personnel carriers, and other armored combat vehicles. Armor targets are small size and very hard. Typical anti-armor warheads include shape charge warhead, explosively formed penetrator (EFP) warhead, and kinetic energy warhead. Anti-armor missiles include Hellfire/Brimstone, LOCAAS, MGM-140 ATACMS, AGM-65 Maverick, and TRIGAT.

A final category is **buried targets**. Buried targets require a high fineness kinetic energy penetration warhead, followed by blast fragmentation. Buried targets include underground command posts and bunkers. Examples of missiles in this category include CALCM, GBU-28, and GBU-31 JDAM.

Alternatives for Precision Strike

Figure 4 compares an assessment of alternatives in establishing mission requirements for precision strike missiles. The assessment of alternatives includes the approaches that are used today by current systems, as

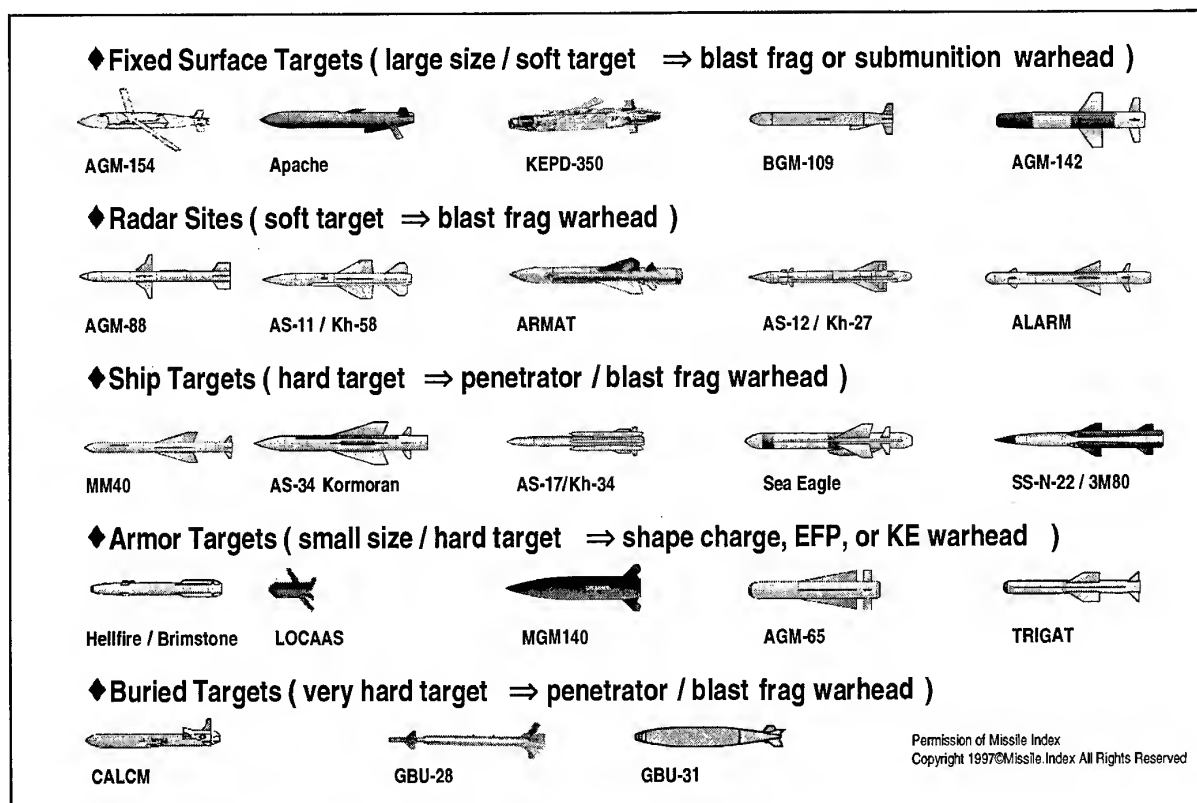

Figure 3. Examples of Precision Strike Missiles.

well as a projection of capabilities that may be used in the foreseeable future for new missile systems. Three measures of merit are shown in comparing future precision strike missiles with current systems. These are cost per shot, number of launch platforms required, and effectiveness against time critical targets. For the current systems, two approaches are used: 1) penetrating aircraft with relatively short range subsonic precision guided munitions and 2) standoff platforms (ships or aircraft) using subsonic cruise missiles. The penetrating aircraft systems include F-117 with subsonic precision guided munitions such as JDAM. As shown in Figure 4, penetrating aircraft/subsonic precision guided munitions have an advantage of low cost per shot. For example, JDAM costs about \$10,000. However, the experience in Desert Storm showed a weakness in the capability of penetrating aircraft to counter time critical targets such as theater ballistic missiles (TBMs). Although there were many aircraft on patrol for SCUDs, the aircraft were never in the right place at the right time. Another current approach, using standoff platforms such as ships and large aircraft outside the threat borders requires fewer launch platforms, resulting in lower logistics costs. However, standoff platforms with subsonic cruise missiles (e.g., Tomahawk, CALCM) are also ineffective against time critical targets (TCTs) such as theater ballistic missiles.

Threat TCTs include (1) mobile theater ballistic missile (TBM) launchers, (2) surface-to-air missile (SAM) systems, (3) command, control and communication (C3) sites, (4) storage and support sites

for weapons of mass destruction, and (5) other time critical strategic targets such as parked aircraft, bridges and transportation choke points. Mobile TBMs and SAMs are of particular interest. TBMs have short timelines, low signature, and high mobility associated with a "hide-scoot-shoot-scoot-hide" doctrine. Time critical events such as leaving a camouflage/concealment site, moving to a launch site, preparing for launch, tearing down after launch, and moving to a camouflage/concealment site are usually observed too late for current subsonic weapons to provide an effective counter-force response. Stationary dwell time of TBMs may be less than 10 minutes.

Because the location of TCTs is often uncertain or their appearance is sudden, the response capability of current approaches is insufficient. An alternative approach is required.

Figure 4 also shows future missile system alternatives for precision strike. Technology work is under way in all three areas, the most cost-effective approach has yet to be determined. One approach is based on a standoff platform, with an aircraft or ship standing off outside the threat country border. Hypersonic long-range precision strike missiles would provide broad coverage, holding a large portion of the threat country at risk. This approach is attractive in the small number of launch platforms required and the effectiveness against time critical targets. The cost of future hypersonic missiles is expected to be comparable to that of the current cruise missiles, such as Tomahawk.

Alternatives for Precision Strike	Cost per Shot	Number of Launch Platforms Required	TCT Effectiveness
<u>Future Systems</u>			
◆ Standoff platforms / hypersonic missiles	○	●	◐
◆ Overhead loitering UCAVs / hypersonic missiles	◐	◐	●
◆ Overhead loitering UCAVs / subsonic PGMs	●	○	◐
<u>Current Systems</u>			
◆ Penetrating aircraft / subsonic PGMs	●	—	—
◆ Standoff platforms / subsonic missiles	○	●	—
Note: ● Superior ◐ Good ○ Average — Poor			
Note: C4ISR targeting state-of-the-art for year 2010 projected to provide 2 minutes target – shooter connectivity and target location error (TLE) less than 1 meter.			

Figure 4. Projected Future Capability of Precision Strike Missile Systems.

Another alternative approach is to use overhead loitering unmanned combat air vehicles (UCAVs) with hypersonic missiles. The number of UCAVs required is dependent upon the speed and range of their on-board precision strike missiles. This approach would probably provide the fastest response time against time critical targets, because of the shorter required missile flight range for an overhead loitering system.

A third approach is overhead, loitering UCAVs with subsonic precision guided munitions. This approach would have the lowest cost per shot, but would also require a relatively large number of UCAVs.

An enabling synergistic capability for precision strike is the application of near real time, accurate targeting from either overhead tactical satellite or overhead unmanned air vehicle (UAV) sensors. It is expected that an advanced command, control, communication, computers, intelligence, surveillance, reconnaissance (C4ISR) network will be available in the year 2010 time frame to support near-real-time and high accuracy targeting of time critical targets. Figure 5 illustrates an example of a ground station, overhead satellite sensors and satellite relays, and overhead UAV sensor platform elements of the C4ISR architecture. The

assumed C4ISR of the year 2010 is projected to have a capability for a target location error (TLE) of less than 1 meter (1 sigma) and sensor-to-shooter connectivity time of less than 2 minutes (1 sigma).

The improved responsiveness of hypersonic precision strike missiles must be harmonized with other measures of merit such as robustness, warhead lethality, miss distance, observables, survivability, reliability, and cost, as well as constraints such as launch platform integration and firepower requirements (Figure 6).

Figure 7 summarizes the technology development and design validation process for precision strike missile systems. The technology development is focussed on the key enabling technologies that are driven by the requirements, but are in need of additional development and demonstration for a required level of maturity. The technology development addresses alternative approaches, risk mitigation, exit criteria for each phase, and an exit plan in the event of failure. The technology development and demonstration activities lead to a level of readiness for entry into Engineering and Manufacturing Development (EMD).

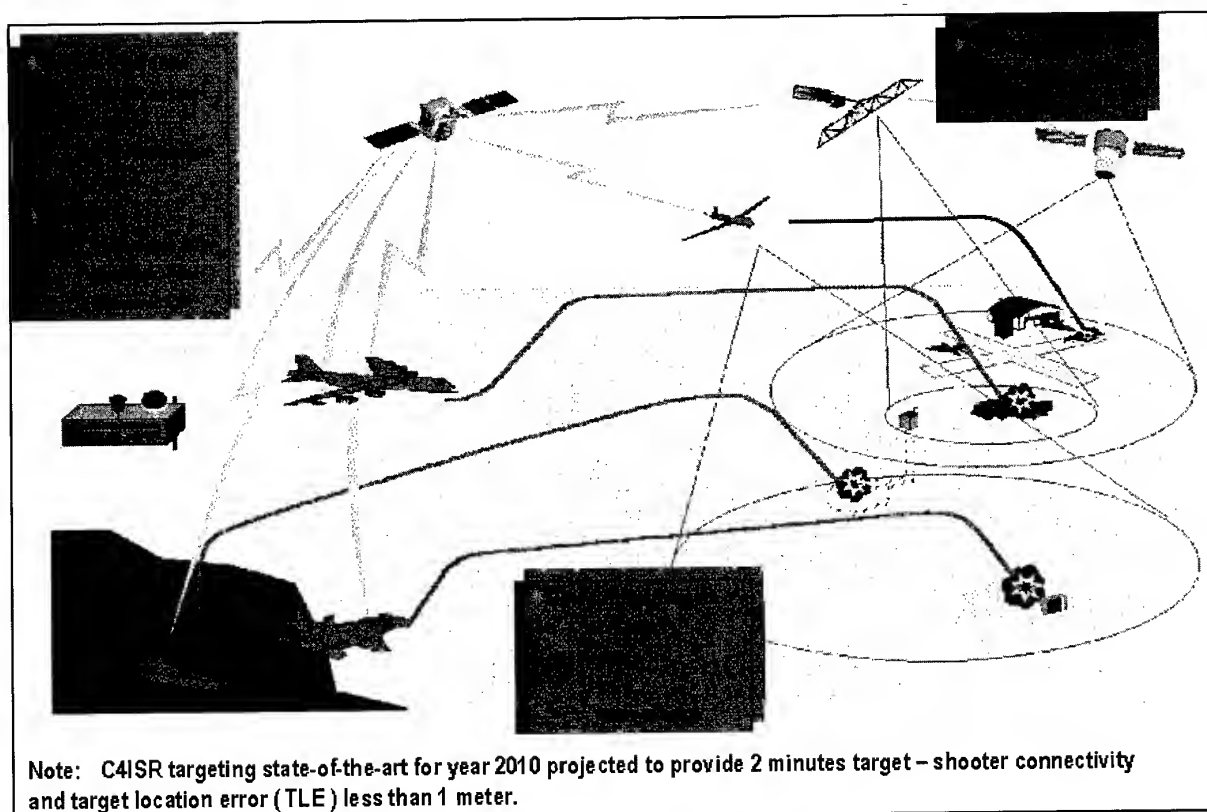

Figure 5. Future C4ISR Tactical Satellites and UAVs Will Provide Targeting Against Time Critical Targets.

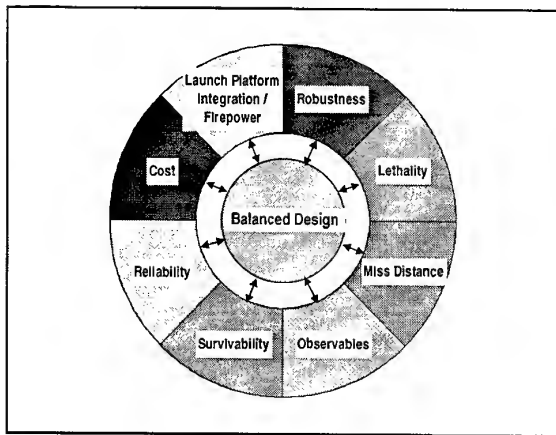

Figure 6. Measures of Merit and Launch Platform Integration Should Be Harmonized.

Early technology work addresses laboratory tests and demonstrations of critical components in a representative environment, but not necessarily a full-scale environment. The next step of technology development is a laboratory or flight demonstration of a full-scale component in a full-scale environment. This is followed by either a laboratory demonstration or a flight Advanced Technology Demonstration (ATD) of a full-scale subsystem in a full-scale environment of the Concept Definition Phase. Finally, there is a flight demonstration, based on either an Advanced Concept Technology Demonstration (ACTD) or a full-scale prototype in a full-scale environment. This is required for a precision strike missile to enter into EMD.

A primary tool in the design validation/development process is missile system simulation. Initial simulations used in conceptual and preliminary design are digital simulations. As missile guidance & control hardware becomes available, a hardware-in-loop (HWL) simulation is also developed. The HWL simulation incorporates missile guidance & control hardware (e.g., seeker, gyros, accelerometers, actuators, autopilot). It also includes a simulated target signal for the seeker to track. Hybrid computers are used in HWL simulation. Fast analog computers simulate the rapidly changing parameters, such as the flight trajectory. Digital computers simulate the more slowly changing parameters, such as the forces and moments from aerodynamics and propulsion. HWL and digital simulations are the primary system analysis tools used during missile flight tests. For example, simulation results based on wind tunnel data are validated with flight test results. HWL and digital simulations are also used to determine the cause of flight test anomalies.

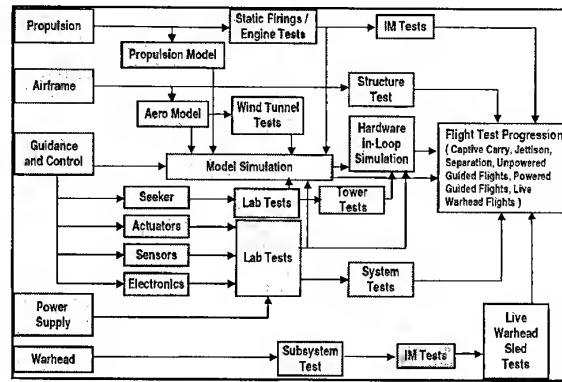

Figure 7. Design Validation/Technology Integration Is An Integrated Process.

New Technologies for Precision Strike Missiles

Figure 8 summarizes new technologies for precision strike missiles. Most of these were covered in this lecture series, however there was insufficient time to address them in detail. Almost all subsystems in precision strike missiles are expected to have major technology improvements in the future. The following is an assessment of new technologies for precision strike missiles, following the format of Figure 8.

Dome. New seeker/sensor dome technologies include faceted/window, multi-spectral, and multi-lens domes.

Faceted domes are pyramidal-shaped domes that have reduced dome error slope, resulting in improved guidance accuracy. Seeker tracking errors due to the error slope of a traditional high fineness dome are a problem for imaging infrared and radar seekers. Small changes in the curvature of a dome greatly affect the tracking accuracy. An approach that alleviates the problem, previously developed for the Mistral and SA-16 missiles, is a faceted dome. The SLAM ER precision strike missile and ballistic missile defense interceptors also use a similar approach, based on a single flat window. A faceted dome behaves in the same optical manner as a flat window dome, with an advantage of a wider field of regard available to the seeker. The error slope of a faceted/window dome is nearly negligible compared to a traditional high fineness dome. Another advantage of a flat window is reduced observables. A grid or slotted film over the wavelength or frequency of interest. This results in reduced radar scatter, providing reduced radar cross section (RCS) for the precision strike missile.

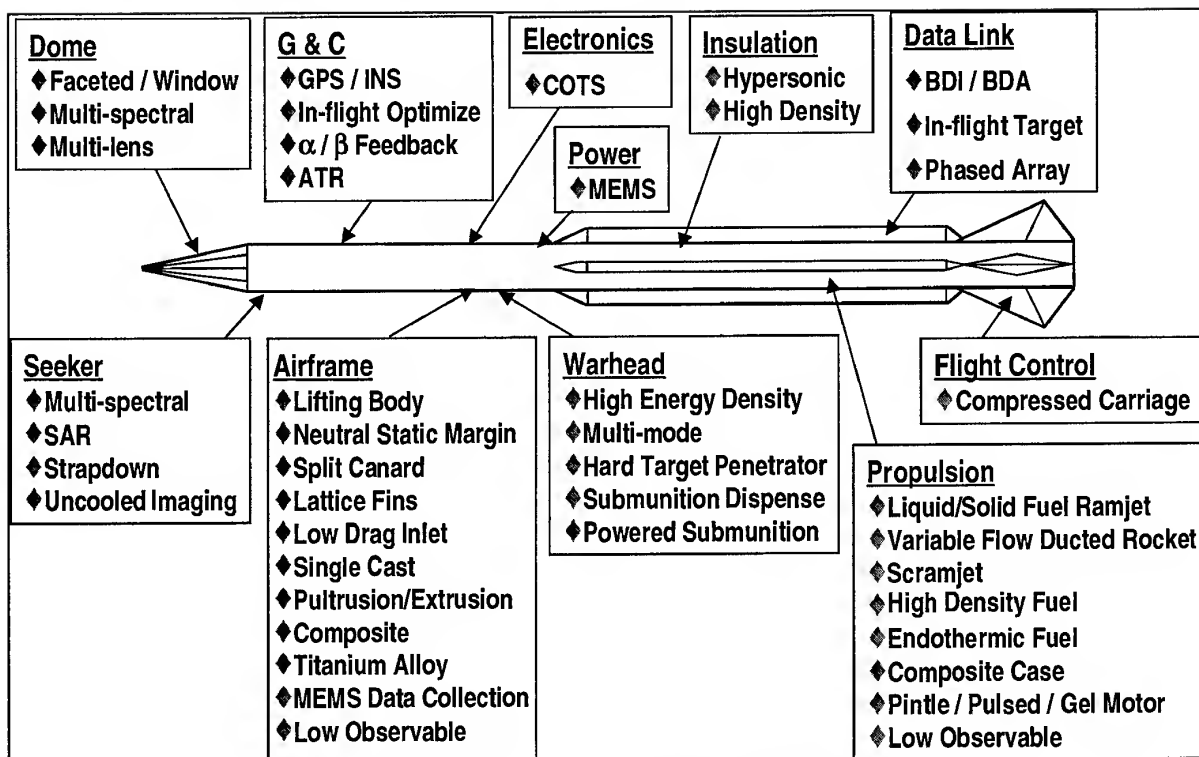

Figure 8. New Technologies for Precision Strike Missiles.

Another dome technology is multi-spectral domes. Multi-spectral domes allow multi-spectral (e.g., mid-wave IR/long wave IR) and multi-mode (e.g., IR/millimeter wave) seekers.

Multi-lens domes are concentric high fineness domes that provide optical correction, resulting in low dome error slope. A high fineness multi-lens dome has lower drag at supersonic speed than a traditional hemispherical dome.

Seeker. New seeker technologies include multi-spectral, synthetic aperture radar (SAR), strapdown, and uncooled IR seekers.

Multi-spectral/multi-mode seekers provide enhanced performance for automatic target recognition. As an example, imaging IR focal plane array (FPA) detectors have the capability to sample multiple wavelengths, providing multi-spectral target discrimination across a broad wavelength. Multi-spectral seekers also have enhanced rejection of false targets and ground clutter.

SAR seekers have good effectiveness in adverse weather and ground clutter. SAR seekers have the flexibility to cover a broad area search (e.g., 5 km by 5 km) for single-cell target detection, then switch to high resolution (e.g., 0.3 meter) for target identification and targeting in ground clutter. An example of a SAR sensor is the Predator UAV TESAR. SAR seekers can also provide high-accuracy profiling of the known terrain features around the target and derive the GPS coordinates of the target.

Strapdown seekers are seekers without gimbals, using electronic stabilization and tracking. The reduction in parts count by eliminating gimbals reduces the seeker cost, which may be the highest cost subsystem of a precision strike missile.

Uncooled IR seekers use an uncooled detector, such as a bolometer. Elimination of a cooling system reduces seeker cost.

G&C. Guidance & control technologies include Global Positioning System/Inertial Navigation System (GPS/INS), in-flight guidance optimization, derived angle-of-attack and angle-of-sideslip feedback for bank-to-turn missiles, and automatic target recognition.

GPS/INS of the year 2010 is projected to have a precision guidance capability of less than 3 meters circular error probable (CEP). GPS/INS precision accuracy permits a low cost seeker-less missile to be used against fixed targets.

INS sensors that cost about \$20,000 US a decade ago are now a third of the price. The potential exists for a \$2,000 to \$3,000 INS, based on Micro-machined Electro-Mechanical Systems (MEMS) technology. MEMS devices are fabricated from a single piece of silicon by semiconductor manufacturing processes, resulting in a small, low-cost package. Between 2,000 and 5,000 MEMS gyro devices can be produced on a single five-inch silicon wafer.

INS sensor alternatives for precision strike missiles include those based on ring laser gyros, fiber optic gyros, digital quartz gyros, and MEMS gyros/accelerometers.

Benefits of GPS/INS integration include higher precision position and velocity measurement, reduced sensor noise, reduced jamming susceptibility, and missile attitude measurement capability. A missile operating at high altitude with a modern GPS receiver will have lower susceptibility to jamming. The availability of GPS to continuously update the inertial system allows the design trades to consider a lower precision and less expensive INS, while maintaining precision navigation accuracy (3 meters CEP) and good anti-jam (A/J) performance.

Modern GPS/INS receivers are based on a centralized Kalman filter that processes the raw data from all of the sensors (e.g., SAR, GPS receiver, INS). GPS/INS Kalman filters with more than 70 states have been demonstrated for precision strike missiles. In addition to enhanced accuracy, Kalman filters also provide robustness against jamming and the loss of satellites. Pseudo-range measurements can be made from three, two, or even one satellite if one or more of the satellites are lost.

Using in-flight digital trajectory flight prediction and derived flight conditions (e.g., Mach number, angle of-attack, angle-of-sideslip, dynamic pressure) from the GPS/INS, the missile can continuously optimize the flight trajectory to maximize performance parameters such as range, off-boresight, and accuracy.

Automatic target recognition will continue to improve as a technology, relieving the workload of the pilot. Advancements in sensor capability for C4ISR will provide new capabilities of near real-time ATR, lower false alarm rate, improved targeting accuracy, and improved data rate.

Electronics. Referring to Figure 8, a fourth area of enabling capability is electronics technology. Revolutionary advancements have been made in high performance, low cost commercial off-the-shelf (COTS) processors. This is an enabling technology for guidance & control and sensor data fusion. The capability to process multi-dimensional discrimination in a low cost, small size, and low power package is beginning to emerge. Processing capability has been doubling about every two years, expanding from 2,300 transistors on the 4004 chip in 1972 to 5.5 million transistors on the Pentium Pro chip in 1995. There is no sign that the growth rate will slow down. A projection to the year 2010 predicts a capability of over 1 billion transistors on a chip. Processing capability is ceasing to be a limitation for the application of sensor data fusion and near real-time trajectory optimization to precision strike missiles.

Airframe. Airframe technologies are enhancing flight performance, reducing weight, permitting higher flight Mach number, reducing cost, providing higher reliability, and reducing observables. Airframe technologies for precision strike missiles include non-axisymmetric lifting bodies, neutral static margin, split canard, lattice fins, low drag inlets, single cast structures, pultrusion/extrusion manufacturing, composites, titanium alloys, MEMS data collection, and low observables.

Lifting body airframes provide enhanced maneuverability and aerodynamic efficiency (lift-to-drag ratio). Enhancements in maneuver and cruise performance are also provided by neutral static margin. Split canard control also provides enhanced maneuverability. Another airframe technology that has high payoff for supersonic precision strike missiles is lattice fins. Lattice fins have advantages of smaller hinge moment and higher control effectiveness. Another airframe technology is low drag inlets. Low drag inlets are in development for hypersonic missiles.

New airframe technology will also reduce the cost of precision strike weapons. Examples of recent precision strike weapons that include low cost technologies include JDAM and JASSM. Technologies to reduce cost are also being introduced into existing weapons, with large savings. An example is Tactical Tomahawk. It has a simple low cost airframe with extruded wings that enables the introduction of low cost commercial parts for G&C and propulsion. The current Tomahawk has 11,500 parts, 2,500 fasteners, 45 circuit cards, 160 connectors, and 610 assembly/test hours. Tactical Tomahawk will have 35% fewer parts, 68% fewer fasteners, 51% fewer circuit cards, 72% fewer connectors, and 68% fewer assembly/test hours – resulting in a 50% reduction in cost. The Tactical Tomahawk also has superior flexibility (e.g., shorter mission planning time, a capability for in-flight targeting, a capability for battle damage indication/battle damage assessment, modular payload) and higher reliability. Tactical Tomahawk demonstrates that reduced parts count is an important contributor to reducing missile cost. The traditional approach to estimating missile unit production cost has been to base the cost estimate on missile weight. However, Tactical Tomahawk is the same weight as the current Tomahawk, at 50% of the cost.

Precision castings will become more prevalent in precision strike missiles. Castings reduce the parts count, with a resulting cost savings. This technology is particularly important to air breathing missiles such as ramjets, which have a more complex nonaxisymmetric shape. Ramjets have traditionally been more expensive than axisymmetric rocket powered missiles. A one-piece cast airframe design integrates all of the secondary structure to minimize

the structure parts count. Precision tooling minimizes subsequent machine and hand finishing of mating surfaces, by achieving a precision surface finish "as-cast." Fuel cells can be an integral part of the structure and not require bladders. Structural attachment points (e.g., ejector attachments, payload supports, booster attachments) and self-indexing/aligning features can be integral to the structure. This minimizes or eliminates mating, alignment, and assembly tooling and test (inspection) requirements. Precision castings have been demonstrated for missile aluminum, titanium, and steel airframes, motor cases, and combustors. Ceramic tooling is an enabling technology for low cost precision castings.

Other manufacturing technologies that reduce airframe cost include pultrusion and extrusion manufacturing of the missile structure.

Composite materials will find increased use in new missile airframe structure. High temperature composites particularly have benefits for hypersonic missiles, which require weight reduction. Another technology is titanium alloys. Titanium alloy technology enables lighter weight missiles for a hypersonic, high temperature flight environment.

Future precision strike missiles will have low cost/small size MEMS sensors for data collection during missile development and for health monitoring after production. Localized stress, temperature, and other environmental conditions can be monitored through many sensors scattered around the airframe.

Finally, the airframe shaping and materials technology development for low observable cruise missiles will provide future reduction in observables.

Power. Power supply technology is also expected to benefit from the application of MEMS. The energy per weight available from a MEMS power system is much greater than that of thermal batteries. Micro turbine generator technology is based on micro-machined semiconductor manufacturing techniques. It is basically a miniature generator that is powered by a miniature jet engine. A micro turbine generator offers a greater than 15 to 20 times weight and volume advantage.

Warhead. Enhanced warhead technologies for precision strike missiles include high energy density warheads, multi-mode warheads, hard target penetrator warheads, submunition dispense, and powered submunitions.

Current high explosive warheads have cross-linked double base (XLDB) explosive charges such as HMX and RDX. An example of a new high explosive charge is the US Navy China Lake CL-20. CL-20 is chemically related to current XLDB nitramine explosives. However, CL-20 is a cyclic polynitramine,

with a unique caged structure that provides higher crystal density, heat of formation, and oxidizer-to-fuel ratio. CL-20 propellant has 10-20% higher performance than HMX and RDX. CL-20 also has reduced shock sensitivity (class 1.3 versus 1.1) and milder cookoff reaction than either HMX or RDX.

There is emphasis to reduce unit production cost and logistics cost by producing a multipurpose missile that covers a broader range of targets. An example is the Joint Standoff Weapon (JSOW). JSOW is a neck-down replacement of Walleye, Skipper, Rockeye, Maverick, and laser guided bombs. A multipurpose weapon system for precision strike is inherently flexible because it can engage a broader target set. A modular warhead provides enhanced capability to engage and defeat hardened, buried targets, and mobile surface targets.

Warheads for penetrating deeply buried targets are based on a kinetic energy penetration warhead case that includes a small explosive charge. The technology for kinetic energy penetrator warhead includes penetrator shape, case material, explosive, and fuze to survive and function at high deceleration.

Submunition dispense and powered autonomous submunitions such as LOCAAS have the capability to counter mobile, time critical targets such as TBMs. A powered submunition can search a relatively large area, providing the potential for locating a TBM launcher after the launch site has been vacated. This provides robustness against uncertainties in the time lines for C4I and target dwell. A technical challenge is supersonic/hypersonic dispense of submunitions. The flight environment of high dynamic pressure and shock wave-boundary layer interaction is relatively unexplored. Aft dispense of submunitions is an enabling technology for supersonic/hypersonic submunition dispense.

Insulation. Referring again to Figure 8, an eighth area of enabling capability is insulation technology. Higher density external airframe and internal insulation materials are in development for hypersonic missiles. Most precision strike missiles are volume-limited rather than weight limited. Higher density insulation materials permit more fuel/propellant, resulting in longer range.

Propulsion. Emerging propulsion technologies include liquid/solid fuel ramjet, variable flow ducted rocket, scramjet, high density fuel, endothermic fuel, composite motor case, rocket motor energy management, and low observables.

Turbofan and turbojet propulsion systems are relatively mature technologies for precision strike missiles. They are most suited for subsonic cruise missiles, providing high efficiency to deliver a warhead at long range against non-time-critical targets.

Turbofans/turbojets have an operating regime from Mach 0 to about Mach 3. However, beyond Mach 2, increasingly complex inlet systems are required to match delivered inlet airflow to compressor capacity, and expensive cooling systems are required to avoid exceeding material capabilities at the turbine inlet.

Liquid/solid fuel ramjet propulsion provides high specific impulse for efficient cruise at a Mach number of about 4 and an altitude of about 80,000 feet. Above Mach 5, deceleration of the inlet airflow to subsonic velocity results in chemical dissociation of the air, which absorbs heat and reduces the useful energy output of the combustor. Also, two or more oblique shock compressions are required for efficient inlet pressure recovery at a Mach number greater than 5.0, adding to the complexity, cost, and integration risk of a ramjet missile.

Variable flow ducted rocket propulsion has advantages of higher acceleration than a liquid/solid fuel ramjet and longer range than a solid rocket. For precision strike missions, it is particularly applicable to the suppression of long range, high performance SAMs. The ducted rocket acceleration and fast response to Mach 3+ provides short response time for an anti-SAM engagement. Ducted rockets utilize a gas generator to provide fuel-rich products to the combustor. The fuel-rich products mix and burn with the air from the inlet. The specific impulse of a ducted rocket is between that of a ramjet and a solid rocket.

Supersonic combustion ramjet (scramjet) propulsion is most efficient for cruise Mach numbers 6 or greater. The scramjet maintains supersonic flow throughout the combustor. A technical challenge for the scramjet is fuel mixing and efficient combustion. There are extremely short residence times for supersonic combustion. Another technical challenge is inlet integration for efficient pressure recovery. Like the ramjet, the scramjet is rocket boosted to a supersonic takeover speed. The takeover speed of a scramjet is about Mach 4.5, higher than a ramjet, requiring a larger booster. For a weight-limited system, a scramjet missile will have less available fuel than a ramjet missile. An efficient cruise condition for a scramjet is about Mach 6, 100K feet altitude.

Fuel technologies include high density fuels and endothermic fuels. High density fuels provide high volumetric performance for volume-limited missiles. Endothermic fuels decompose at high temperature into lighter weight molecular products, providing higher specific impulse and permitting shorter combustor length. Endothermic fuels also provide cooling of the adjacent structure.

Another propulsion technology is composite motor cases. Composites provide reduced weight compared to a steel motor case.

Thrust-time history management technologies for rocket motors include pintle, pulsed, and gel propellant motors.

Finally, the emphasis on reduced observable plumes will continue with high emphasis in the foreseeable future.

Data Link. New data link technologies include battle damage indication/battle damage assessment (BDI/BDA), in-flight targeting, and phased array antennas. BDI/BDA can be provided by a data link of target imagery from an imaging IR seeker. In-flight targeting is particularly useful against mobile, time critical targets such as TBMs. Phased array antennas are in development that provide high data rate and flexibility for a precision strike missile to communicate with satellites, ground stations, manned aircraft, and UAVs.

Flight Control. A final area is that of flight control technology for precision strike missiles. The requirement for internal carriage on low observable aircraft has driven new technology in compressed carriage (e.g., small-span/long-chord, folded, wraparound, switchblade) aerodynamic surfaces. This allows higher firepower load-outs for internal carriage on low observable aircraft such as the F-22.

Technologies for Future Precision Strike Missile Systems - Missile Aeromechanics Technology

Abstract/Executive Summary

This paper provides an assessment of the state-of-the-art of new aeromechanics technologies for future precision strike missile systems. The aeromechanics technologies are grouped into specific discussion areas of aerodynamics, propulsion, and airframe materials technologies. Technologies that are addressed in this paper are:

- **Missile aerodynamics technologies.** Assessments include aerodynamic configuration shaping, lattice tail control, split canard control, forward swept surfaces, bank-to-turn maneuvering, and flight trajectory shaping.
- **Missile propulsion technologies.** Assessments include supersonic air breathing propulsion, high temperature combustors, low drag ramjet inlets, ramjet inlet/airframe integration, high density fuels, and rocket motor thrust magnitude control.
- **Missile airframe materials technologies.** Assessments include hypersonic structure materials, composite structure materials, hypersonic insulation materials, multi-spectral domes, and reduced parts count structure.

Introduction

Missile aeromechanics technologies have benefits that include enhanced flight performance, reduced weight, increased Mach number, reduced cost, higher reliability, and reduced observables. Figure 1 summarizes new aeromechanics technologies for precision strike missiles. Most of the technologies in the figure are covered in this paper, however there was not sufficient time to address them all. A summary of other new aeromechanics technologies is presented in the Introduction/Overview paper of this lecture series.

Missile Aerodynamics Technologies

This assessment of missile aerodynamics technologies addresses six new enabling technologies. These are aerodynamic configuration shaping, lattice tail control, split canard control, forward swept surfaces, bank-to-turn maneuvering, and flight trajectory shaping.

Aerodynamic Configuration Shaping. Figure 2 illustrates aerodynamic configurations that are highly

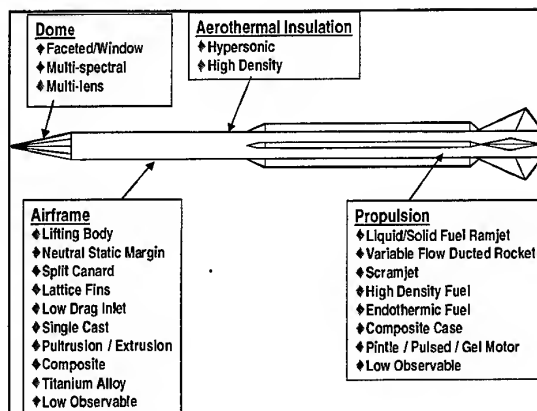

Figure 1. New Aeromechanics Technologies for Precision Strike Missiles.

tailored, using aerodynamic shaping of lifting body configurations. An advantage of a tailored lifting body missile is higher aerodynamic efficiency (lift-to-drag ratio) for extended range cruise performance and enhanced maneuverability. Also shown in Figure 2 is the synergy of tailored missiles with reduced radar cross section. Tailored missiles are also synergistic with ramjets for areas such as inlet integration and liquid hydrocarbon fuel packaging. Disadvantages of tailored missiles include relative inefficiency for subsystem packaging and adverse impact on launch platform integration due to a larger span.

Lattice Tail Control. Another example of new aeromechanics technology is lattice tail control. Lattice fins have advantages of lower hinge moment and higher control effectiveness at supersonic Mach number. Figure 3 shows a comparison of lattice tail control with two conventional approaches to tail control - all movable control and flap control. Except for radar cross section, lattice tail control has good-to-superior performance for supersonic missiles. Also shown in the figure are examples of supersonic missiles with tail control alternatives of lattice tail control (Adder AA-12), all movable tail control (ASRAAM AIM-132), and flap tail control (Hellfire AGM-114). The smaller chord length of the lattice has less variation in the center of pressure, resulting in lower hinge moment for lattice tail control.

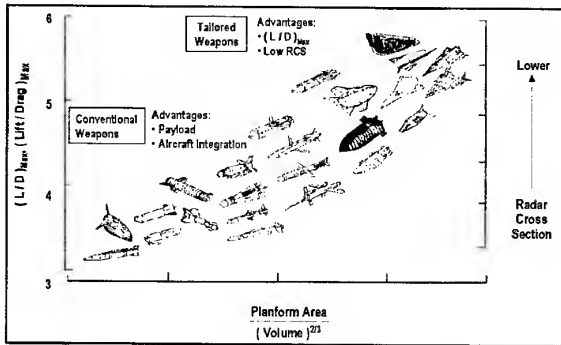

Figure 2. Aerodynamic Shaping Provides Reduced Observables and Higher $(L/D)_{Max}$.

Lattice fins are most appropriate for supersonic missiles. At transonic Mach number, lattice fins have higher drag and lower control effectiveness than traditional flight control. At a low transonic free stream Mach number less than 1, the local flow through the lattice accelerates to Mach 1, choking the flow. For a transonic free stream Mach number slightly greater than 1, the flow through the lattice remains choked. A detached, normal shock wave in front of the lattice spills excess air flow around the lattice. The lattice remains choked until the supersonic Mach number is sufficiently high to allow the lattice to swallow the shock. An oblique shock is then formed on the leading edge of each surface of the lattice. At low supersonic Mach number the oblique shock angle is large. Each oblique shock is reflected downstream, off an adjacent lattice surface, resulting in increased drag. At higher Mach number the oblique shock angle is smaller, passing through the lattice without intersecting a lattice surface. Lattice fins have their best application at high supersonic Mach number, where they have lower drag and higher control effectiveness.

Split Canard Control. Modern highly maneuverable missiles are using split canards for flight control. Split canard control has a flat surface in front of the movable canard. Figure 4 is a schematic of the local flow that illustrates the advantage of split canards.

Figure 4. Split Canards Provide Enhanced Maneuverability at High Angles of Attack.

Figure 3. Lattice Tail Control Provides High Control Effectiveness and Low Hinge Moment.

The incremental normal force coefficient, ΔC_N , in the figure is the difference between the normal force coefficient of the deflected control surface and the normal force coefficient of an undeflected control surface. Note that the forward surface reduces the local effective angle of attack (AOA). Because the trailing canard control surface has a smaller local angle of attack, it is more effective at higher control surface deflection, δ , and higher angle of attack, α , operating without stall. All modern canard control missiles use split canard control including Kegler AS-12, Archer AA-11, Aphid AA-8, Magic R-550, and Python 4.

Forward Swept Surfaces. Forward swept surfaces are an alternative to the traditional aft swept surfaces for missile canards, tails, and wings. Forward swept surfaces are particularly beneficial for missiles that have small span requirements for aircraft compatibility. Figure 5 is a comparison of a forward swept leading edge surface with conventional planform surfaces that are triangular (delta), trapezoidal with an aft swept leading edge, and rectangular. In addition to a smaller span requirement, forward swept surfaces have good-to-superior characteristics of low variation in aerodynamic center, low bending moment, low supersonic drag, low radar cross section, and high control effectiveness. An

Figure 5. Forward Swept Surfaces Allow Small Span and Have Low Bending Moment.

Figure 6. Bank-to-Turn Provides Higher Maneuverability

inherent disadvantage of a forward swept surface is increased potential for aeroelastic instability. Composite structure is synergistic with forward swept surfaces because the higher stiffness of composites mitigates aeroelastic instability.

Bank-to-turn Maneuvering. Figure 6 compares bank-to-turn maneuvers with maneuver alternatives of skid-to-turn and rolling airframe. Missiles using bank-to-turn will first roll until the wings or the major axis of a lifting body are oriented perpendicular to the target line-of-sight. Following the roll maneuver, the missile then maneuvers in pitch, maintaining the preferred roll orientation. A benefit of bank-to-turn maneuvering is higher maneuverability for a lifting body with noncircular cross section or for a missile with wings. Another benefit is smaller sideslip angle for missiles with inlets. Bank-to-turn is particularly suited for mid-course guidance maneuvers. A disadvantage of bank-to-turn maneuvering is slower response in terminal maneuvers that could degrade guidance accuracy, increasing the missile miss distance. Alternative approaches to alleviate this problem include faster actuators for roll control, faceted or multi-lens dome, and switching from bank-to-turn maneuvering to skid-to-turn maneuvering for terminal flight.

Flight Trajectory Shaping. Figure 7 illustrates the extended range advantage of precision strike missiles that use flight trajectory shaping. Flight trajectory shaping is particularly beneficial for high performance supersonic missiles, which have large propellant or fuel weight fraction. To take advantage of flight trajectory shaping, the missile must rapidly pitch up and climb to an efficient cruise altitude. During the climb, the missile angle-of-attack should be small, to minimize drag. Missile thrust-to-weight ratio should also be relatively low (~ 2). Thrust-to-weight ratios greater than about two result in high dynamic pressure, increasing drag. After reaching higher altitude, the missile benefits from cruising at improved lift-to-drag ratio, or aerodynamic efficiency. Dynamic pressure

Figure 7. Flight Trajectory Shaping Provides Extended Range.

for efficient cruise of a high performance supersonic missile is of the order of 500 to 1,000 pounds per square foot. Following burnout, the missile can also have extended range through glide at a dynamic pressure of about 700 pounds per square foot.

Missile Propulsion Technologies

The assessment of missile propulsion technologies addresses six new enabling technologies. These are supersonic air breathing propulsion, high temperature combustors, low drag ramjet inlets, ramjet inlet/airframe integration, higher density fuels, and rocket motor thrust magnitude control.

Supersonic Air Breathing Propulsion. Ramjets, scramjets, and ducted rockets have high payoff for precision strike missiles operating at supersonic/hypersonic Mach number. A comparison of the specific impulse performance of ramjet, scramjet, and ducted rocket propulsion, along with that of solid rocket and turbojet propulsion, is given in Figure 8.

Turbojet and turbofan propulsion is a relatively mature technology for precision strike missiles. Turbojets/turbofans are most suited for subsonic cruise missiles, providing high efficiency to deliver a warhead at long range against non-time-critical targets. The operating regime is from Mach 0 to about Mach 3. However, beyond Mach 2, increasingly complex inlet systems are required to match delivered inlet airflow to compressor capacity, and expensive cooling systems are required to avoid exceeding material capabilities at the turbine inlet.

Solid rockets are capable of providing thrust across the entire Mach number range. Although the specific impulse of tactical rockets is relatively low, of the order of 250 seconds, rockets have an advantage of much higher acceleration capability than air-breathing propulsion. Solid rocket boosters are used to boost ramjets to their take-over Mach number of about 2.5, for transition to air-breathing propulsion.

The maximum specific impulse of a liquid hydrocarbon fuel ramjet is about 1500 seconds, much

Figure 8. Ramjets and Scramjets Have High Payoff at Supersonic/Hypersonic Mach Number.

higher than the specific impulse of a solid rocket. An efficient cruise condition for a ramjet is about Mach 4, 80K feet altitude. Above Mach 5, deceleration of the inlet airflow to subsonic velocity results in chemical dissociation of the air, which absorbs heat and reduces the useful energy output of the combustor. Ramjets are synergistic with noncircular, lifting body airframes because ramjet fuel can be stored in noncircular tanks. Liquid fuel ramjets can be throttled, for efficient matching of the fuel with the inlet airflow. Throttling provides higher thrust and specific impulse over a broader flight envelope of Mach number and altitude. A high throttle setting also allows supersonic impact and deep penetration of buried targets.

Above Mach 6, a supersonic combustion ramjet (scramjet) provides higher performance than a ramjet. The minimum sustained flight Mach number of a scramjet, based on providing sufficient thrust to overcome missile drag, is greater than about Mach 4.0. The maximum Mach number, based on engine material temperature limit, is about Mach 8 to 9. An efficient cruise condition for a scramjet is about Mach 6, 100K feet altitude. A key technical challenge is fuel mixing for efficient supersonic combustion. There are extremely short residence times for supersonic combustion. An enabling technology to enhance supersonic combustion is endothermic fuels. Endothermic fuels decompose at high temperature into lighter weight molecular products that burn more readily, providing higher specific impulse and permitting shorter combustor length. An endothermic fuel also acts as a heat sink, cooling the adjacent structure. Like the ramjet, the scramjet is rocket boosted to a supersonic takeover speed. Takeover speed of a scramjet is higher than a ramjet, about Mach 4.5, requiring a larger booster. For a weight-limited system, a hypersonic scramjet missile will have less available fuel than a supersonic ramjet missile.

Referring again to Figure 8, note that the maximum specific impulse of ducted rocket propulsion is about

Figure 9. State-of-the-Art Evolution in Supersonic/Hypersonic Air Breathing Missiles.

800 seconds, intermediate that of a solid rocket and a ramjet. Ducted rockets are most efficient for a Mach number range from about 2.5-4.0. Ducted rockets have advantages of higher acceleration capability (higher thrust) than ramjets and longer range capability (higher specific impulse) than solid rockets. A ducted rocket is particularly suited for the suppression of long range, high performance SAMs. The acceleration and fast response to Mach 3+ provides a short response time for an anti-SAM engagement. Ducted rockets utilize a gas generator to provide fuel-rich products to the combustor. The gas generator flow rate can be controlled, providing a throttle capability for thrust magnitude control. Air from the inlet mixes with the fuel-rich products from the gas generator, providing additional burning. The relatively high acceleration capability of the ducted rocket is due to the momentum of the gases from the gas generator. A disadvantage of the ducted rocket is lower specific impulse than a ramjet. Because the gas generator includes an oxidizer, the total energy stored in the gas generator is less than that of a ramjet or scramjet fuel tank of the same volume. In addition to a relatively high thrust capability of a ducted rocket compared to a ramjet or scramjet, a solid ducted rocket has advantages of lower maintenance requirements and better shipboard compatibility than a liquid fuel ramjet or scramjet.

Figure 9 shows a history of the state-of-the-art advancement for supersonic/hypersonic air breathing missiles over the last fifty years. A number of ramjet demonstrations have been conducted over the years. As shown in the figure, the cruise Mach number demonstrations have provided higher confidence in the capability for efficient hypersonic cruise. Ramjets have demonstrated supersonic and hypersonic cruise up to Mach 4.5. A future flight demonstration of a scramjet plans to demonstrate Mach 6.5 cruise in the year 2002 time frame.

High Temperature Combustors. Higher combustion temperature has payoff in improving the specific impulse and thrust of ramjet missiles, enabling flight at higher Mach number. Figure 10 shows the ideal

Figure 10. High Combustor Temperature Has High Payoff at Hypersonic Mach Number.

combustion temperature for maximum specific impulse and thrust of an ideal ramjet as a function of Mach number. Results are based on an assumption of isentropic flow, perfect gas, and nozzle expansion to atmospheric pressure. The state-of-the-art for current combustor material technology is about 5,000 degrees Rankine. At a combustor temperature of 5,000 degrees Rankine, the ratio of combustor temperature to freestream temperature is approximately 15. As shown in the figure, for a combustor temperature ratio of 15, maximum specific impulse for a ramjet is produced at a Mach number of about 3.5. Also shown is the Mach number for maximum thrust per unit frontal area. The maximum thrust per unit frontal area is produced at a Mach number of about 4.7. Future improvement in the technology for maximum allowable temperature of combustor materials will allow ramjets to operate more efficiently at higher Mach number.

Low Drag Ramjet Inlets. Examples of low drag inlet alternatives for ramjets are shown in Figure 11. Current operational ramjets have either a nose inlet (United Kingdom Sea Dart) or aft axisymmetric inlets (France ANS and ASMP, Russia AS-17/Kh-31, Kh-41, and SS-N-22/3M80). A nose inlet has lower drag, while aft axisymmetric inlets are lighter weight, have lower volume, and do not degrade warhead effectiveness.

Ramjet Inlet/Airframe Integration. Because ramjet combustion is subsonic, there must be a normal shock in the inlet to provide subsonic flow into the combustor. Small oblique shocks prior to the normal shock alleviate the problem of total (stagnation) pressure loss across the normal shock. Figure 12 compares a single, normal shock total pressure recovery with that of one, two, and three oblique shocks prior to the normal shock. An example is shown of a chin inlet ramjet that has two oblique shocks (from a conical forebody angle of 17.7 degrees and an inlet ramp angle of 8.36 degrees). As shown in the example, the stagnation pressure recovery ratio at

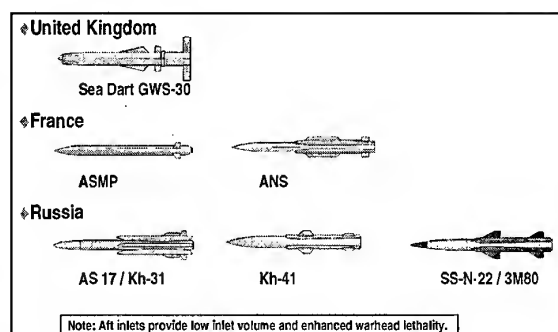

Figure 11. Current Ramjet Inlets Are Either Low Drag Nose or Low Drag Aft Axisymmetric.

Mach 3.5 is 62% if there are two oblique shocks. This stagnation pressure recovery is much higher than that for the case of one oblique shock prior to the normal shock or for the case of a single normal shock. Ramjet inlet/airframe integration through forebody compression (such as a chin inlet) and an optimized inlet cowl lip angle provides higher specific impulse and higher thrust.

High Density Fuels. Another area of new propulsion advancement is that of higher density fuel. Higher density fuels provide high volumetric performance for volume limited missiles (Figure 13). Current fuels for turbines such as JP-5, JP-7, and JP-10 have relatively low density, of the order of 0.028 pounds per cubic inch, and low volumetric performance, of the order of 559 BTUs per cubic inch. Liquid fuel ramjet hydrocarbon fuels such as RJ-4, RJ-5, RJ-6, and RJ-7 have somewhat higher density and higher volumetric performance. Slurry fuels, such as JP-10 with carbon slurry, and solid hydrocarbon fuels have much higher volumetric performance, at the expense of somewhat higher visual observables. Even better performance is achievable with high density, solid metal fuels such as magnesium, aluminum, and boron. For example, solid boron fuel provides over 3X the volumetric performance of liquid hydrocarbon fuels. However, metal fuels have high visual observables from their plumes.

Rocket Motor Thrust Magnitude Control. An approach to energy management for a solid rocket is thrust magnitude control. Alternatives include pulsed and pintle motors (Figure 14). The solid pulsed motor uses thermal or mechanical barriers to separate two or more pulses. The time delay between pulses can be controlled to optimize the flight trajectory profile. As a result, a boost-coast-boost-coast pulsed motor can have longer range and reduced aerodynamic heating compared to a conventional boost-coast motor. The second approach to thrust magnitude control, a solid pintle motor, has a pintle plug that is moved in and out of the throat area. Moving the pintle into the throat area provides increased chamber pressure and higher thrust, while moving the pintle out of the throat area decreases the chamber pressure and thrust. Pintle

Figure 14. Thrust Magnitude Control Provides Efficient Thrust Management.

motors have demonstrated maximum-to-minimum thrust ratios of up to six-to-one. However, larger thrust ratio is at the expense of reduced specific impulse. A third potential alternative for thrust magnitude control is a gel propellant motor. Gel propellants have not yet been accepted for tactical missile applications, particularly for naval platforms, due to concerns of toxicity.

Missile Airframe Materials Technologies

The assessment of missile airframe materials technologies addresses five new enabling technologies. These are hypersonic structure materials, composite structure materials, hypersonic insulation materials, multi-spectral domes, and reduced parts count structure.

Hypersonic Structure Materials. Examples of structure materials that are cost effective for precision strike missiles are shown in Figure 15. The materials are based on consideration of weight, cost, and maximum temperature capability. Composite materials are a new technology that will find increased use in new missile airframe structure. High temperature composites have particular benefits for hypersonic missiles, providing weight reduction. Titanium alloy technology also enables lighter weight missiles in a hypersonic, high temperature flight environment.

As shown in the figure, at subsonic and low supersonic Mach number, graphite epoxy and aluminum or aluminum alloys are attractive choices for light weight structure. Graphite epoxy and aluminum alloys have high strength-to-weight ratio, are easily fabricated, have good corrosion resistance, and are low in cost. For higher Mach number,

Figure 15. Hypersonic Missiles Require High Temperature Structure.

Figure 16. Composites Have High Strength.

graphite polyimide composite structure has the advantage of high structure efficiency at higher temperature for Mach numbers to about Mach 4. For flight at about Mach 4.5, titanium structure and its alloys becomes the best candidate. At Mach 5, although it is heavy, a steel structure would probably be used. Above about Mach 5.7, (about 2,000 degrees Fahrenheit), super nickel alloys such as Inconel, Rene, Hastelloy, and Haynes must be used. The Mach number and temperature application relationships are somewhat dependent upon the temperature recovery factor. At a stagnation region, such as the nose or leading edges, the recovery factor is about 1, resulting in the highest (stagnation) temperature. A turbulent or laminar boundary layer downstream of the nose or leading edge will have temperature recovery factors of about 0.9 and 0.8 respectively, with local temperatures less than stagnation.

Composite Structure Materials. The strength-to-weight capability of advanced composites is very high. For example, as shown in Figure 16, the unidirectional tensile strength of graphite (carbon) fiber is more than 400K pounds per square inch. Advanced composite structures have continuous fibers, greater than 50% fibers by volume. Fibers can be graphite (carbon), kevlar, boron, ceramic, silicon carbide, quartz, polyethylene, and others. As an example of strength at the structure level, 50% volume graphite composite structure would have a strength of the laminate above 200K pounds per square inch, much greater than that of aluminum, or even steel. Also the low density of composites further reduces the weight compared to metals. Graphite fiber composite materials have extremely high modulus of elasticity, resulting in low strain and deflection compared to metals. However, a note of caution, unlike metals that generally yield gracefully before ultimate failure, composite fibers fail suddenly without yield.

Figure 17 shows the structural efficiency advantage of composites compared to conventional materials. For temperatures up to about 300 degrees Fahrenheit, graphite epoxy is a good candidate material, based on

Figure 17. Composites Have High Structural Efficiency.

its characteristics of high strength and low density. Graphite polyimide can be used at even higher temperatures, up to about 900 degrees Fahrenheit. Above 900 degrees Fahrenheit, titanium and steel are the best materials based on strength-to-weight ratio.

Hypersonic Insulation Materials. An area of enabling capability for hypersonic precision strike missiles is short duration insulation technology. Because hypersonic precision strike missiles have stringent volume and weight constraints, higher density external airframe and internal insulation materials are in development. Higher density insulation materials permit more fuel/propellant, resulting in longer range. Thermal insulators are used to provide short duration protection of structural materials from either the aerodynamic heating of a hypersonic free stream or from propulsion heating of the combustion chamber and exhaust gases of the nozzle. Figure 18 shows the maximum temperature and short duration insulation efficiency of candidate insulation materials.

Figure 18. Composites Provide Light Weight Insulation.

Note that composite materials are good candidates for light weight insulation. For high-speed precision strike missiles, relatively high density plastic composites, such as fiberglass reinforced phenolic resins containing nylon, silica, graphite, or carbon are often used. These have good resistance to erosion, allow high surface temperatures up to 5,000 degrees Rankine, and exhibit good insulation performance. High density plastic composite materials char at high temperature, but maintain their thickness and aerodynamic shape. They are usually fabricated by wrapping fiberglass tape over a metal form mandrel, so that the grain of the finished unit is oriented for minimum erosion. Cross flow orientation, or other grain directional orientation, is optimized to minimize the amount of the material that is required. After winding, the tape is cured, machined as necessary, and assembled with other components using adhesives and sealants. Another example of a good insulator at somewhat lower temperatures is low density composites. Low density composites such as glass cork epoxy or silicone rubber may be used for temperatures up to about 2800 degrees Rankine. A disadvantage of low density composites is that at high temperatures they decompose into gases and sublime, resulting in decreased thickness and changes in the aerodynamic shape. Low density composites are also relatively soft, requiring periodic maintenance touch-up.

Ceramic refractory materials and graphite materials are also candidate insulators for hypersonic missiles. Although ceramic refractory materials and graphites have high temperature capability, the insulation efficiency for a given weight of material is not as good

as that of high density plastic composite materials. An example of a porous ceramic, with a maximum temperature up to about 3,500 degrees Rankine, is resin impregnated carbon-silicon carbide. At high temperatures the resin melts, providing cooling for the structure. Examples of bulk ceramics are zirconium ceramic and hafnium ceramic. Bulk ceramics are capable of withstanding temperatures up to 5,000 degrees Rankine, but like porous ceramics, they have relatively poor insulation efficiency. Finally, graphite insulators provide the highest temperature capability. Graphites are capable of withstanding temperatures greater than 5,000 degrees Rankine. Graphites are also known as carbon-carbon, fibrous graphite, prepolymerized composites, graphite-graphite composites, and graphite composites. Graphites are usually formed by pressure molding at a temperature high enough so that all the material has charred and converted to carbon or graphite. Graphites contain a graphite or carbon fabric, fiber, filament, or felt reinforcement bonded together, with carbon or graphite as the bonding material.

Airframe structure/insulation trades include hot structure/internal insulation versus external insulation/"cold" structure versus a one-piece self-insulating composite structure. A consideration for a volume-limited missile is the total thickness of the airframe/insulation. Large thickness means less volume for fuel, resulting in less range.

Multi-spectral Domes. Multi-spectral domes are broad bandpass domes that are compatible with multi-spectral (e.g., mid-wave IR/long wave IR) and multi-mode (e.g., IR/millimeter wave) seekers. Figure 19

Seeker Dome Material	Density (gm/cm ³)	Dielectric Constant	MWIR / LWIR Bandpass	Transverse Strength (psi)	Thermal Expansion (10 ⁻⁶ /°F)	Erosion, Knoop (kg/mm ²)	Max Short-Duration Temp (°F)

Figure 19. Broad Bandpass Domes Support Multi-Mode/Multi-Spectral Seekers.

compares measures of merit for combined radar/infrared dome materials with radar-only and infrared-only dome materials. Measures of merit are dielectric constant, combined mid-wave/long wave infrared bandpass, transverse strength, thermal expansion, erosion resistance, and maximum short duration temperature. Current dome materials that can be used for combined radar and infrared seekers include zinc sulfide and zinc selenide. Zinc sulfide has advantages in dielectric constant and transverse strength, while zinc selenide has an advantage of less rain erosion. Zinc sulfide is generally the multi-mode dome material of choice for Mach numbers up to 3. For Mach number greater than 3, new materials will be required for multi-mode seekers. Candidate materials include spinel, quartz/fused silicon, and silicon nitride. These materials are more expensive than zinc sulfide and zinc selenide. A new candidate dome material that is under development for missile defense applications is diamond. Obviously cost is very high for a diamond dome. In addition to high material cost, diamond dome assembly cost is high. Diamond domes must be assembled as a built-up mosaic because the individual diamonds are relatively small size.

Reduced Parts Count Structure. Airframe cost and producibility are important considerations for precision strike missiles. New airframe technology is in development that will reduce the cost of precision strike weapons. Examples of recent precision strike weapons that include low cost technologies include JDAM and JASSM. Technologies to reduce cost are also being introduced into existing weapons, with large savings. An example is Tactical Tomahawk. It has a simple low cost airframe with extruded wings

that enables the introduction of low cost commercial parts for G&C and propulsion. The current Tomahawk has 11,500 parts, 2,500 fasteners, 45 circuit cards, 160 connectors, and requires 610 assembly/test hours. Tactical Tomahawk will have 35% fewer parts, 68% fewer fasteners, 51% fewer circuit cards, 72% fewer connectors, and 68% fewer assembly/test hours – resulting in a 50% reduction in cost (Figure 20). Tactical Tomahawk also has superior flexibility (e.g., shorter mission planning time, capability for in-flight targeting, capability for battle damage indication/battle damage assessment, modular payload) and higher reliability at the same launch weight as the current Tomahawk.

Precision castings will also become more prevalent in precision strike missiles. Castings reduce the parts count, with a resulting cost savings. Large precision cast structures are in development for complex missile shapes, such as ramjets. A one-piece cast airframe design integrates all of the secondary structure to minimize parts count. Precision tooling minimizes subsequent machine and hand finishing of mating surfaces, by achieving a precision surface finish “as-cast.” Fuel cells can be an integral part of the structure and not require bladders. Structural attachment points (e.g., ejector attachments, payload supports, booster attachments,) and self-indexing/aligning features can be integral to the structure. This minimizes or eliminates mating/alignment/assembly tooling and test (inspection) requirements. Precision castings have been demonstrated for missile aluminum, titanium, and steel airframes, motor cases, and combustors. Ceramic tooling is an enabling technology for low cost precision castings.

Summary

The fundamental ideas and the basic mathematics of the most common missile guidance laws are outlined. Rules of thumb for the required lateral acceleration for the different guidance laws are given.

A brief summary of flight mechanics is given. The pitch axis control is treated and the dynamic properties are identified. Design of the autopilot for the inner loop using modern methods of controller design is briefly outlined.

Introduction

Precision guided weapons have played an increasingly important role in recent conflicts and much media attention has been focused on the surgical precision provided by modern high-tech weapons. However, the concepts behind today's guided weapons date back to the Second World War and in some cases even to the First World War. It is, however, clear that the technological progress has only recently made it possible to fully exploit the concept of guided weapons.

Guidance can be defined as the strategy for how to steer the missile to intercept, while *control* can be defined as the tactics of using the missile control actuators to implement the strategy.

Guidance has normally been divided into:

- Target related guidance, where target tracking data are provided in real time from a sensor, which can be on-board or off-board.
- Non-target related guidance, where the missile navigates to some predetermined point, which can be the target or the point where target related guidance can begin.

As the integration sensor-to-shooter improves and near real time targeting data can be obtained from sensors not tied to the missile system, this distinction becomes less clear. It must also be noted that the performance of affordable navigational systems (integrated GPS/INS) offers precision in the order of meters. Weapons using non-target related guidance, such as JDAM, can hence compete with traditional homing missiles.

Mid-course guidance and trajectory optimisation

A case of partially target related guidance is mid-course guidance, where the missile is guided to the vicinity of the target using target data from an external sensor. Most long range weapons designed against mobile targets employ mid-course guidance. Examples of this are air-to-air missiles such as AMRAAM.

Air-to-air missiles often employ trajectory optimisation during the mid-course. The main reason for this is to exploit the lower drag at higher altitude. Optimisation can be used to obtain minimal time of flight, maximal range, maximal terminal velocity etc.

Trajectory optimisation can also be used for air-to-surface weapons to obtain a favourable angle of impact, no angle of attack at impact etc. The performance of penetrating warheads can be greatly improved by terminal trajectory optimisation.

A further use for trajectory optimisation can also be route planning, where the missile's flight path is planned to avoid obstacles, maximise survivability, maximise the probability of target acquisition etc. This planning is normally done prior to launch, but re-planning can be done in flight by the missile.

Advances in computational power and optimisation algorithms have now made it possible to use real time optimisation in flight.

Guidance Laws

The most fundamental, and also most commonly used, guidance laws are:

- Velocity Pursuit
- Proportional Navigation
- Command-to-Line-of-Sight
- Beam Riding

All of these guidance laws date back to the very first guided missiles developed in the 1940's and 1950's. The reasons that they have been so successful are mainly that they are simple to implement and that they give robust performance.

Velocity pursuit is used mainly in the first generations of laser guided bombs, e.g. Paveway I and II. Proportional navigation is used in almost all homing missiles. Command-to-line-of-sight is used in short to medium range missiles without seekers, e.g. most anti-tank missiles and many surface-to-air missiles. Beamriding is not so common, but it is found in surface-to-air missiles such as RBS70 and ADATS.

The presentation in this paper is mainly based on Assarsson. For further reading on missile guidance there are several good textbooks, e.g. Blakelock, Garnell, Lee, and Zarchan.

Velocity Pursuit

The conceptual idea behind velocity pursuit guidance is that the missile should always head for the target's current position. Provided that the missile's velocity is greater than the target's, this strategy will result in an intercept.

The required information for velocity pursuit is limited to the bearing to the target, which can be obtained from a simple seeker, and the direction of the missile's velocity. Velocity pursuit is usually implemented in laser guided bombs, where a simple seeker is mounted on a vane, which automatically aligns with the missile's velocity vector relative to the wind. The mission of the guidance and control system thus becomes to steer the bomb such that the target is centred in the seeker.

Figure 1. Velocity pursuit kinematics.

Using a target fixed polar coordinate system, see figure 1, the equations describing the kinematics of velocity pursuit are

$$\dot{r} = v_T \cdot \cos \phi - v_M$$

$$r \cdot \dot{\phi} = -v_T \cdot \sin \phi$$

Integration gives

$$r = r_0 \cdot \frac{(1 + \cos \phi_0)^{\frac{v_M}{v_T}}}{(\sin \phi_0)^{\frac{v_M}{v_T}}} \cdot \frac{(\sin \phi)^{\frac{v_M}{v_T}-1}}{(1 + \cos \phi)^{\frac{v_M}{v_T}}}$$

where index 0 denotes the initial condition.

An observation from the above equation is that intercept (when r approaches zero) occurs at either $\phi=0$ or $\phi=\pi$, i.e. tail-chase or head-on. As the head-on case proves to be unstable, the only feasible case is the tail-chase intercept.

Figure 2. Trajectory and required lateral acceleration for a velocity pursuit missile. $v_M=2v_T$.

The velocity pursuit guidance law results in high demanded lateral acceleration, in most cases infinite at the final phase of the intercept. As the missile cannot perform infinite acceleration, the result is a finite miss distance.

Velocity pursuit is thus sensitive to target velocity and also to disturbances such as wind. The velocity pursuit guidance law is not suitable for meter precision.

Proportional Navigation

The conceptual idea behind proportional navigation is that the missile should keep a constant bearing to the target at all time. As most sailors know this strategy will result in an eventual impact.

The guidance law that is used to implement this concept is

$$\dot{\gamma} = c \cdot \dot{\phi}$$

where γ is the direction of the missile's velocity vector, ϕ is the bearing missile to target, and c is a constant. Both of the angles γ and ϕ are measured relative to some fixed reference.

Figure 3. In the ideal collision triangle both the target and the missile move with constant velocity and the bearing to the target is constant throughout the trajectory.

With angles as defined in figure 4 and using polar coordinates the following kinematic equations in the 2D case can be obtained:

$$r\dot{\phi} = v_M \cdot \sin(\phi - \gamma) - v_T \cdot \sin \phi$$

$$\dot{r} = -v_M \cdot \cos(\phi - \gamma) + v_T \cdot \cos \phi$$

$$\dot{\gamma} = c \cdot \dot{\phi}$$

A linearised model of the kinematics can be obtained by considering deviations denoted by Δ from the ideal collision triangle denoted by index 0.

$$\phi = \phi_0 + \Delta\phi$$

$$\gamma = \gamma_0 + \Delta\gamma$$

$$\gamma_T = \gamma_{T0} + \Delta\gamma_T$$

where γ_T is the direction of the target's velocity vector relative to the reference.

The equations for the disturbances thus become:

$$\frac{d}{dt}(\Delta\phi \cdot r) = -v_M \cdot \cos(\phi_0 - \gamma_0) \cdot \Delta\gamma +$$

$$+ v_T \cdot \cos(\phi_0 - \gamma_{T0}) \cdot \Delta\gamma_T$$

$$\dot{r} = -v_M \cdot \cos(\phi_0 - \gamma_0) + v_T \cdot \cos(\phi_0 - \gamma_{T0}) \approx -v_c$$

$$\frac{d}{dt}(\Delta\gamma) = c \cdot \frac{d}{dt}(\Delta\phi)$$

where the closing velocity v_c has been introduced.

Figure 4. Proportional navigation, kinematics and definition of angles.

The time-to-go, τ , is introduced as

$$\tau = \frac{r}{v_c}$$

From the equations can be observed that

$$\dot{\gamma} = -\frac{c \cdot v_M \cdot \cos \phi_0}{\tau \cdot v_c} \cdot \gamma + \dots$$

It can be concluded that the factor

$$\frac{c \cdot v_M \cdot \cos \phi_0}{\tau \cdot v_c}$$

is of significant importance to the performance of the guidance law.

So far the guidance law has been formulated with the rotation of the velocity vector as the variable to be controlled. However, a more natural variable to control is the missile's lateral acceleration. As the closing velocity, which is found in the loop gain above, varies greatly with the geometry of the intercept, altitude, target type etc, it is desirable to include the closing velocity in the guidance law.

Hence

$$n_M = \alpha \cdot v_C \cdot \dot{\phi}$$

The parameter α is called the navigation constant and should be between 3 and 4 (maybe up to 5) to ensure good dynamic performance. A value of α greater than 2 is required for the missile to intercept manoeuvring targets.

This formulation requires a measurement or an estimate of the closing velocity. If the missile uses active radar homing, a measurement of the closing velocity can be obtained using Doppler technology. In most other cases a rough estimate can be obtained from the geometry of the engagement and the altitude.

From the equations above an expression for the required missile acceleration to intercept a manoeuvring target can be derived as:

$$\frac{n_M}{n_T} = \frac{\cos \phi_0}{\cos(\phi_0 - \gamma_0)} \cdot \frac{\alpha}{\alpha - 2} \cdot \left[1 - \left(\frac{\tau}{\tau_0} \right)^{\alpha-2} \right]$$

Where τ_0 has been introduced as the total time of flight and n_T is the target load factor. In the head on or tail chase scenarios this can be simplified and especially if the endgame, where τ approaches zero, is considered, the following expression is obtained:

$$\left| \frac{n_M}{n_T} \right| = \frac{\alpha}{\alpha - 2}$$

As α normally is between 3 and 4, this rule of thumb gives that a homing missile should be designed to perform three times the target's possible lateral acceleration.

Augmented Proportional Navigation

The proportional navigation guidance law gives the missile good performance against targets moving with constant velocity. If the target acceleration can be measured, it is possible to augment the PN guidance law by adding a term to compensate for the target acceleration. The Augmented Proportional Navigation (APN) guidance law thus becomes

$$n_M = \alpha \cdot \left(v_C \cdot \dot{\phi} + \frac{1}{2} \cdot n_T \right)$$

For APN the required lateral acceleration of the missile given by a target manoeuvre can be derived as

$$\frac{n_M}{n_T} = \frac{1}{2} \cdot \alpha \left(\frac{\tau}{\tau_0} \right)^{\alpha-2}$$

The maximal acceleration thus becomes

$$\frac{n_M}{n_T} = \frac{1}{2} \cdot \alpha$$

Or, as α is between 3 and 5, about twice the target load factor. It can furthermore be observed that the maximal acceleration occurs at the initiation of the evasive manoeuvre, while for the PN law it occurs at the more critical final phase of the intercept.

However, before declaring the augmented proportional navigation law as superior to PN, the dynamic performance and the robustness relative to disturbances have to be considered.

The missile is here assumed to be a third order system, i.e.

$$\frac{n_M}{n_c} = \frac{1}{(1 + sT) \cdot \left(1 + \frac{2\zeta s}{\omega} + \frac{s^2}{\omega^2} \right)}$$

with the following numerical values:

$$\omega = 10 \text{ rad/s}$$

$$\zeta = 0.7$$

$$T = 0.5 \text{ s}$$

The missile furthermore has a navigational constant of 3 and the target manoeuvres with a load factor of 3g. Then the miss distance as function of time to go at the initiation of the target manoeuvre and of the accuracy with which the target's acceleration can be estimated is shown in figure 5.

The conclusion from the dynamic analysis of the APN law is that the superior performance relative to PN is clearly sensitive to errors in the estimation of the target manoeuvre. It can also be noted that it is especially bad to over estimate the target acceleration. This sensitivity is certainly a reason for the limitations faced by APN in practical use.

Figure 5. Miss distance in meters as function of time to go at the initiation of the target manoeuvre (t_F) and ratio between the estimated target acceleration and the actual acceleration.

Command-to-Line-of-Sight and Beam Riding

Both Command-to-Line-of-Sight (CLOS) and Beam Riding (BR) use the same fundamental idea, i.e. that the missile should be on the straight line between the launcher and the target throughout the trajectory. That guidance law can be called line-of-sight guidance or three point guidance.

Figure 6. The kinematics of line-of-sight guidance.

With terminology according to figure 6 and with r_M and r_T the distances from the missile fire unit to the missile and to the target respectively, the equations describing line-of-sight guidance can be expressed in polar coordinates as:

$$r_M \cdot \dot{\phi}_M = -v_M \cdot \sin(\phi_M - \gamma_M)$$

$$\dot{r}_M = v_M \cdot \cos(\phi_M - \gamma_M)$$

If the first equation is derived with respect to the time and divided by the second, the following equation is obtained:

$$\dot{\gamma}_M = \left(2 - \frac{\dot{v}_M}{v_M} \cdot \frac{r_M}{\dot{r}_M} \right) \cdot \dot{\phi}_M + \frac{r_M}{\dot{r}_M} \cdot \ddot{\phi}_M$$

The equation for the target can be expressed similarly as

$$\dot{\gamma}_T = \left(2 - \frac{\dot{v}_T}{v_T} \cdot \frac{r_T}{\dot{r}_T} \right) \cdot \dot{\phi}_T + \frac{r_T}{\dot{r}_T} \cdot \ddot{\phi}_T$$

Ideal line-of-sight guidance implies that

$$\phi_M \equiv \phi_T$$

The missile equation can thus be written as

$$\dot{\gamma}_M = \left(2 - \frac{\dot{v}_M}{v_M} \cdot \frac{r_M}{\dot{r}_M} \right) \cdot \dot{\phi}_T + \frac{r_M}{\dot{r}_M} \cdot \left[\frac{\dot{r}_T}{r_T} \cdot \dot{\gamma}_T - \left(2 \frac{\dot{r}_T}{r_T} - \frac{\dot{v}_T}{v_T} \right) \cdot \dot{\phi}_T \right]$$

If

$$\dot{v}_T = 0$$

$$\dot{v}_M = 0$$

i.e. constant velocity is assumed for both missile and target, the equation becomes

$$\dot{\gamma}_M = \left(2 - \frac{r_M}{\dot{r}_M} \cdot \frac{\dot{r}_T}{r_T} \right) \cdot \dot{\phi}_T + \frac{r_M}{\dot{r}_M} \cdot \frac{\dot{r}_T}{r_T} \cdot \dot{\gamma}_T$$

The first term in this equation gives the manoeuvre required for the missile to keep up with the rotation of the line-of-sight, while the second term gives the manoeuvre required to counter a target manoeuvre. An analysis of the second term, using the facts that the missile generally is between the launcher and the target and also generally moving away from the launcher with greater velocity than the target, i.e.

$$r_M < r_T$$

$$\dot{r}_M > \dot{r}_T$$

shows that the manoeuvrability requirement generated by target manoeuvres is less than the target load factor and that it increases closer to intercept. This is in contrast to the manoeuvre requirement for proportional navigation which is about three times the target load factor.

The dominating manoeuvrability requirement on line-of-sight guided missiles is usually not generated by target manoeuvres but by target velocity. The requirement for a short inner limit to the launch zone is often the driving requirement.

Figure 7. Trajectory of a line-of-sight guided missile.

The required lateral acceleration can be expressed as

$$n_M = 2 \frac{v_M \cdot v_T}{d} \beta$$

where β is an acceleration factor obtained from the diagram in figure 8. d is the crossrange, i.e. the minimal perpendicular distance between the

target's trajectory and the fire unit, and ϕ is angle between the line-of-sight and the missile velocity vector.

Both CLOS and BR rely on a tracking sensor in connection to the launcher to track the target continuously during the intercept. In a CLOS system the tracking sensor tracks both the target and the missile and measures the angular difference between the two objects. Control commands are then calculated based on the desire to drive the angular difference between the missile and the target to zero, and these commands are subsequently transmitted to the missile.

In a beamrider system the fire unit projects a beam that continuously tracks the target. This beam can be generated by a laser or by an RF transmitter. The missile has a sensor in its rear, that measures the deviation from the centre of the beam and the missile flight control system seeks to minimise that deviation.

Although the guidance law is the same for CLOS and BR, the former implementation enjoys an advantage as the calculation of the command signals can use more information than just the present deviation from the line-of-sight. The use of the rotation of the line-of-sight as a feed-forward term can significantly decrease the miss distance.

Both CLOS and BR are limited in range, as the target tracking errors, which are the results of angular measurements at the launch site, generate miss distances proportional to the range.

Characteristics of the Guidance Laws

The characteristics of the treated guidance laws are summarised in the table below.

Guid. law	Acc due to target velocity	Acc due to target acceleration	Required measurement
VP	infinite	infinite	Angle between target bearing and velocity vector
PN	Zero	$3 \cdot n_T$	Rotation of bearing to target
APN	Zero	$2 \cdot n_T$	Rotation of bearing to target and target acceleration
CLOS	High at short range	$< n_T$	Angular deviation from line-of-sight
BR	High at short range	$< n_T$	Angular deviation from line-of-sight

Figure 8. Diagram giving β .

Control

An autopilot is a function that improves the flight performance of the vehicle by using feed-back of some of the state variables, such as angular velocities and accelerations, obtained from rate gyros and accelerometers respectively.

The mission of the control system in the missile autopilot is to ensure stability, high performance, and that the missile flies in accordance to the demands from the guidance law. The most important objective is to design the control system such that the miss distance is minimised given relevant disturbances such as target evasive manoeuvres, measurement noise, jamming, wind etc.

The missile dynamics to be controlled are given by Newton's equation for a rigid body in 6 degrees of freedom:

$$\sum \mathbf{F} = \frac{d}{dt}(m\mathbf{v})$$

$$\sum \mathbf{M} = \frac{d\mathbf{H}}{dt}$$

Or explicitly as six equations, and with the assumption of constant mass:

$$F_x = m(\dot{u} + wq - vr)$$

$$F_y = m(\dot{v} + ur - wp)$$

$$F_z = m(\dot{w} + vp - uq)$$

$$M_x = \dot{p}I_{xx} - \dot{r}I_{xz} + qr(I_z - I_y) - pqI_{xz}$$

$$M_y = \dot{q}I_{yy} + pr(I_{xx} - I_{zz}) + (p^2 - r^2)I_{xz}$$

$$M_z = \dot{r}I_z - \dot{p}I_{xz} + pq(I_{yy} - I_{xx}) + qrI_{xz}$$

Where

$\mathbf{F}=(F_x, F_y, F_z)$ is the external force vector

$\mathbf{v}=(u, v, w)^T$ is the velocity vector

$\mathbf{M}=(M_x, M_y, M_z)$ is the moment vector

\mathbf{H} is the angular momentum vector

$\boldsymbol{\omega}=(p, q, r)$ is the angular velocity vector

\mathbf{I} is the inertia matrix

The external forces and moment are those generated by the aerodynamic forces, including control surfaces, the propulsion, including control thrusters, and by gravity. The six equations of motion given above are non-linear and coupled. This is further complicated by the fact that the aerodynamic forces are highly non-linear, especially at high angles of attack, and coupled.

The control problem of employing the control actuators in a suitable way to achieve good performance and stability thus becomes a non-linear multivariable control problem. The classical approach to this problem is to linearise around an operating point and then study the control of one variable at a time. There are at least two very severe restrictions to this approach: a missile rarely flies at a trimmed equilibrium, and the states of a missile are normally coupled to each other.

Flight mechanics and controls are treated in many textbooks, e.g. Blakelock. A simplified example of missile control in a 2D, pitch direction case is given below.

Figure 9. Definitions of variables for the pitch control problem.

Nomenclature:

m	Missile mass
u	Missile velocity
q	Dynamic pressure
d	Body diameter
S	Cross section area
I	Moment of inertia
ℓ_0	Distance between centre of pressure and centre of gravity
ℓ	Distance between tail rudder and centre of gravity
C_{Na}	Aerodynamic derivative, normal force per unit of angle of attack
C_{Ns}	Aerodynamic derivative, normal force per unit of rudder deflection
C_{mq}	Aerodynamic derivative, moment per unit of body rotation rate
$C_{m\alpha}$	Aerodynamic derivative, moment per unit of angle of attack

With variables defined in figure 9 the linearised equations of motion become:

$$\ddot{\theta} = \frac{qS}{I} \left(-\ell_0 C_{Na} \alpha - \ell_i C_{Ns} + \frac{d^2}{2u} C_{mq} \dot{\theta} \right)$$

$$\dot{\gamma} = \frac{qS}{mu} (C_{Na} + C_{Ns} \delta)$$

$$\dot{\alpha} = \dot{\theta} - \dot{\gamma}$$

The transfer function between velocity vector rotation rate and rudder angle becomes

$$\frac{\dot{\gamma}}{\delta} = k_0 \frac{(1 + \tau_1 s)(1 + \tau_2 s)}{1 + 2\zeta_0 s / \omega_0 + s^2 / \omega^2}$$

With the following values of gain k_0 , eigenfrequency ω_0 and damping ζ_0 .

$$k_0 \approx -\frac{qSC_{Ns}}{mu} \frac{\ell_i - \ell_0}{\ell_0}$$

$$\omega_0 \approx \sqrt{\frac{\ell_0 qSC_{Na}}{I}}$$

$$\zeta_0 \approx \frac{1}{2u} \left(\frac{I}{m} - \frac{d^2 C_{mq}}{2C_{Na}} \right) \sqrt{\frac{qSC_{Na}}{I\ell_0}}$$

where it has been assumed that

$$\frac{qSd^2 C_{mq}}{2mu^2 \ell_0} \ll 1$$

These equations show that the fundamental dynamic properties of the missile can vary greatly with velocity, altitude, mass, inertia etc.

The control system should be designed to give the missile sufficient stability and responsiveness for all relevant flight conditions. To design a single controller for all flight conditions is normally not possible. As a consequence many missile controllers use gain scheduling, where a set of operating points are chosen from the set of possible flight conditions. For each of these points the non-linear missile dynamics is linearised and a controller is designed. A scheme for choosing between the controllers, i.e. the gain scheduling, based on some varying parameters such as dynamic pressure and angle of attack is then formulated.

Recent advances in controller design have, however, made it possible to design the controller for all flight conditions at the same time. The currently most promising technique for this is Linear parameter varying (LPV) design, where the plant is assumed to have the form

$$\dot{x}(t) = A(\theta(t))x(t) + B(\theta(t))u(t)$$

$$y(t) = C(\theta(t))x(t) + D(\theta(t))u(t)$$

where x is the state variable vector, y is the output, u is the control input and θ is a vector of measured variables. An overview of current issues in missile controller design is found in Ridgely and McFarland.

Bank-to-turn

Most missiles are roll stabilised in an X or + configuration and use the control actuators to achieve the desired direction of the lateral acceleration. There are, however, missiles where the roll channel has to be given close consideration.

Bank-to-turn guidance requires the missile to manoeuvre with the lateral acceleration in a single body fixed direction. In order to manoeuvre, the missile first has to bank to align the body with the desired direction. Bank-to-turn guidance can be used to decrease the number of control surfaces, and consequently the drag, and can also be required by the propulsion system. Air breathing propulsion such as ramjets can normally only operate under limited variations of angle of attack and can also be sensitive to side slip.

Trends

Advances in algorithms and computational power will provide missiles with greater manoeuvrability, particularly at high angles of attack, and improved capabilities to optimise the trajectory.

However, the most important trends in the field of guidance and control can be all be described under the label of "integration":

- Integrated inertial and satellite navigation will provide all sorts of guided weapons with high precision at low cost. Important aspects are the development of small solid state inertial components for use in the automotive industry, and the continuous improvement of the GPS system.
- Integration between guidance and control offers a potential to improve performance. The established division between slower, outer loop guidance and faster, inner loop control can be dissolved using more advanced algorithms.
- Integration between the missile and overall C⁴ISR system will become tighter. High precision targeting can be provided almost in real time. This will enable low cost weapons using precision navigation to attack many targets without using an expensive seeker.

Abstract

The goal of this paper is to explore emerging post Cold War missile seeker requirements that will lead to new seeker procurements in the year 2000+. These requirements are compared to existing missile seeker products to show where technology deficiencies exist. A projection is made of what seekers will be deployed in the near future to fill important military missile user needs and where technology investments will be made to develop fully capable missile seekers. The orientation of the presentation is on missile seekers as a product and the functionality they provide the military user community. Therefore, the presentation discusses new functionality not included in seekers built in the 1900's because of technology limitations or lack of sufficient user requirements.

Introduction

The 1900's has brought the development of precision munitions and established a base for major improvements in missile seekers during the next millenium. This paper addresses what new missile

seekers will enter military inventory during the first part of the new millenium based on developing post cold war requirements for missile seekers. This paper will focus on what the author believes are a few key requirements that will drive missile seeker developments and technology investments. Missile seekers will be viewed more from a product and customer need prospective rather than a technology perspective.

Flying Into The New Millenium

At the end of this millenium, technology appears to be king and advances appear to move at a very rapid pace. Commercial technology truly appears to be flying into the next millenium. Major advances in military technology are equally impressive although held back some by a post cold war restructuring of the military/industrial complex. This restructuring raises questions not only about what the mission of the military will be in the early part of the new millenium and what equipment fills that need but how industry makes a profit and stays solvent in a shrinking market. Figure 1 illustrates this pivotal time in military history

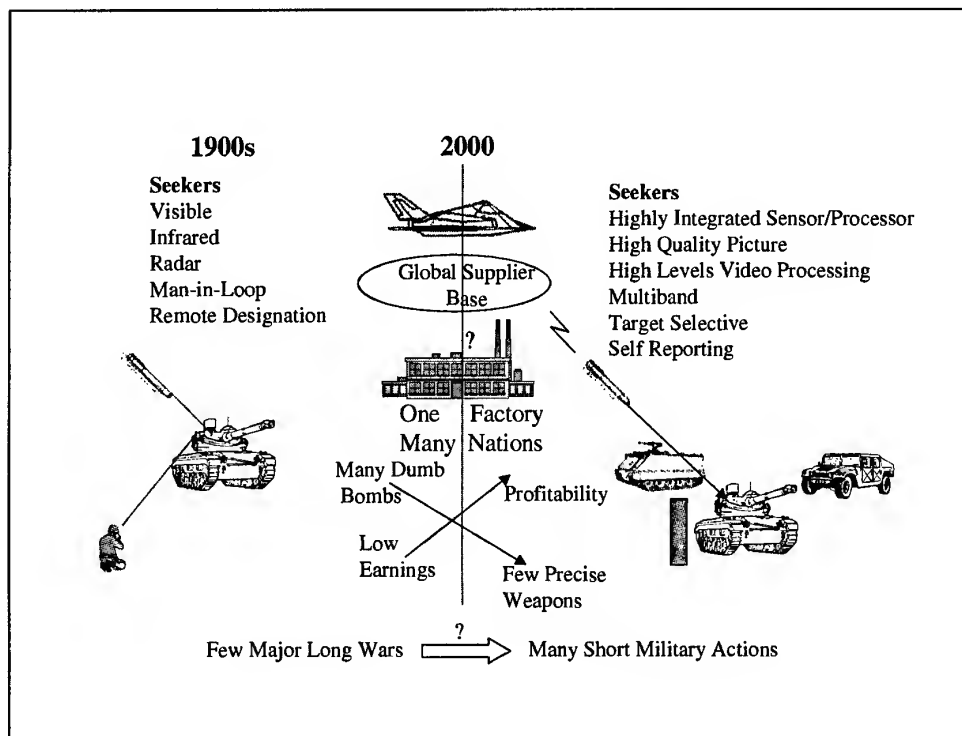

Figure 1 Flying Into The New Millenium

Paper presented at the RTO SCI Lecture Series on "Technologies for Future Precision Strike Missile Systems", held in Atlanta, USA, 23-24 March 2000; Turin, Italy, 3-4 April 2000; Ankara, Turkey, 6-7 April 2000, and published in RTO-EN-13.

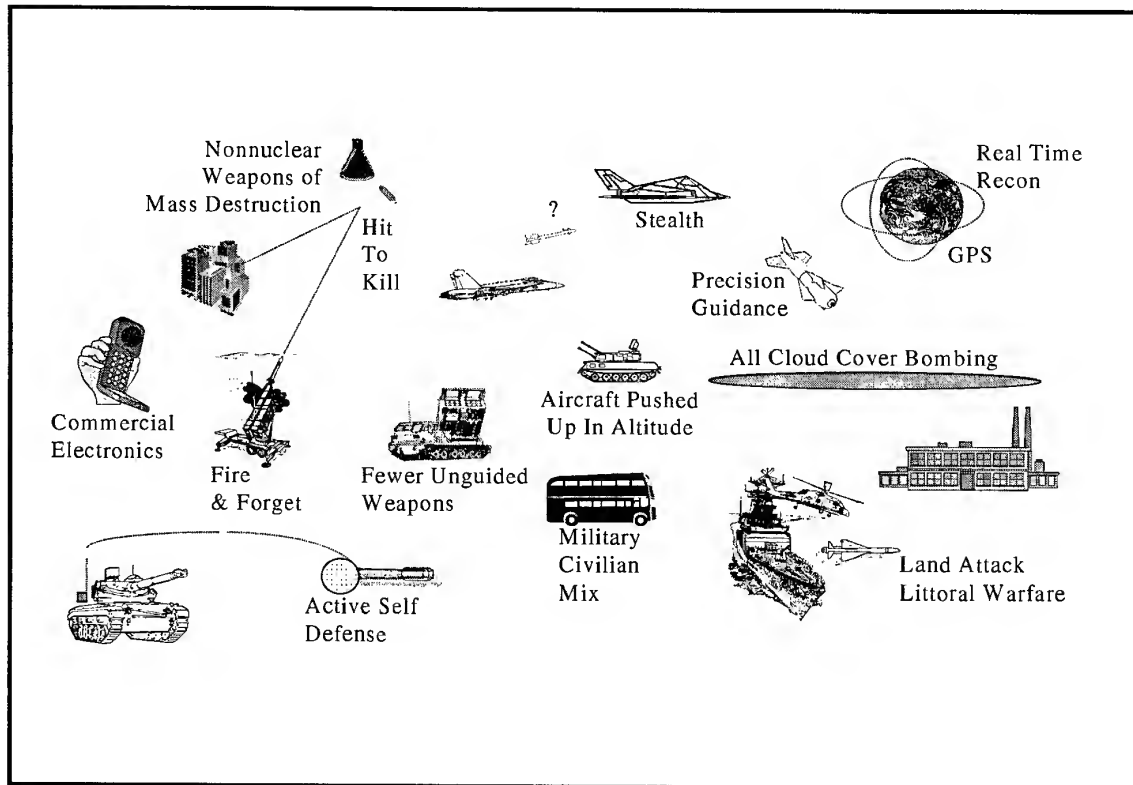

Figure 2 Changing Seeker Requirements

and the need to adjust rapidly to a world going through major military and geopolitical changes. In spite of the many uncertainties, there are new requirements emerging for a new generation of more capable missile seekers which industry will have to fill in a more economical fashion than in the past. Because commercial technology appears to be moving at a faster pace than military technology, filling these needs more economically may require finding a way to exploit commercial products without major compromises in military preparedness.

Seeker Functions

The reason a seeker is put in a missile is because there is uncertainty in the missile launch point, flight path or target location that makes it impossible to achieve the desired accuracy without a seeker. For some targets and bomb sizes, GPS accuracy is sufficient and a seeker is not required to satisfy mission objectives. Seekers can also provide autonomy allowing the launch aircraft to move out of the range of air defenses or move to the next target more rapidly. It is helpful to keep this functionality in mind when reviewing requirements and the needs for new seekers.

A new developing seeker function is real time, bomb impact reporting that helps determine the need for a second weapon on target. Since an increasing number

of seekers are imaging seekers, the potential exists to transmit the pictures back to the launch aircraft or support aircraft just prior to weapon impact. This doesn't verify warhead detonation but verifies correct aimpoint selection. Depending on the reliability of the fuse and warhead, bomb detonation can be assumed to have occurred.

Changing Seeker Requirements

In the opinion of the author seeker requirements have and will change dramatically during the next millenium in many mission areas as illustrated in Figure 2. Seekers built during the 1900s were designed for major world wars rather than small wars with a high likelihood of friendly forces intermixed with enemy forces or weapons of mass destruction hidden in civilian areas.

New seeker requirements include antistealth, hit-to-kill at an affordable price, and in the area of strike warfare both the Desert Storm and Kosovo operations demonstrated the need to attack through the clouds and engage targets autonomously. Filling these newer and in some cases older requirements with technology that may finally have reached the required level of maturity will be a high priority task of military planners.

Impact of GPS on Missile Seekers

The introduction of GPS has had an impact on missile seeker developments and is worthy of some discussion but the impact is not what some military planners hoped it would be. Some military planners hoped that GPS would reduce seeker requirements, and therefore, reduce the procurement cost of seekers. To some extent they have reduced fixed target search requirements but this hasn't had a major impact on seeker costs. GPS has had a major impact on dumb bombs by providing a way of reducing their dispersion through the introduction of INS/GPS tailkits and perhaps the final days of dumb bombs will come to pass.

Figure 3 illustrates what the author sees as the real impact of GPS on seekers for mission areas such as strike warfare. First the introduction of an INS/GPS has meant that the INS becomes the source of high rate autopilot commands instead of the seeker providing high bandwidth line-of-sight rate information. The seeker becomes a low rate navigation update device to the INS. This gives imaging systems and ATR systems more time to perform their processing relaxing throughput requirements on the ATR. Fixed target ATR is clearly reduced since the ATR knows the precise approach range and angles.

A final point about GPS is its use in the military strategic and tactical mission areas plus commercial applications. The use of GPS to guide weapons means any attempt to negate the effective of GPS is a threat to all three of these communities and perhaps the

commercial application is the one of greatest value to the voting public. Attempts to destroy GPS satellites could also raise a conflict to the level of nuclear warfare.

Future Investments, Technology Thrusts and New Products

Future investments leading to new technologies and products will be driven as always by those needs the military decides have the highest priority modified some by political considerations as illustrated in Figure 4. Figure 4 lists some needs the author believes military planners have or will decide are a high priority such as cloud penetration or high impact angle in the area of strike warfare. In the current technology base are E/O and radar seekers of various forms and in the research base are some new types such as imaging passive MMW plus multisensor. Cloud penetration will create a need for a radar seeker of some form. In the authors opinion, this is most likely a synthetic aperture radar seeker and this will drive industry to invest in affordable SAR designs through lean manufacturing, certified suppliers and use of commercial products. These initial radar designs will have to develop solutions for the high impact angle requirement since radars have difficulties when transmitting straight into the ground.

As figure 5 illustrates, there is a need for each type of seeker depending on the mission area. Each of these developments compete for the same pool of production dollars.

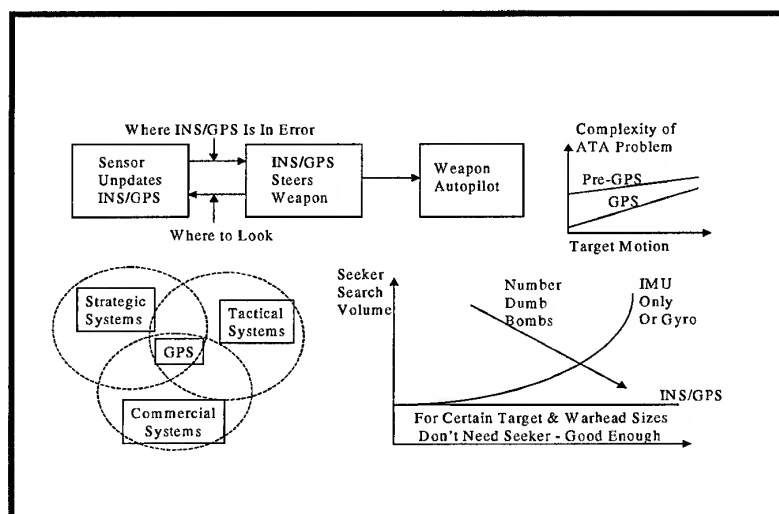

Figure 3 GPS Impact on Seeker Operation

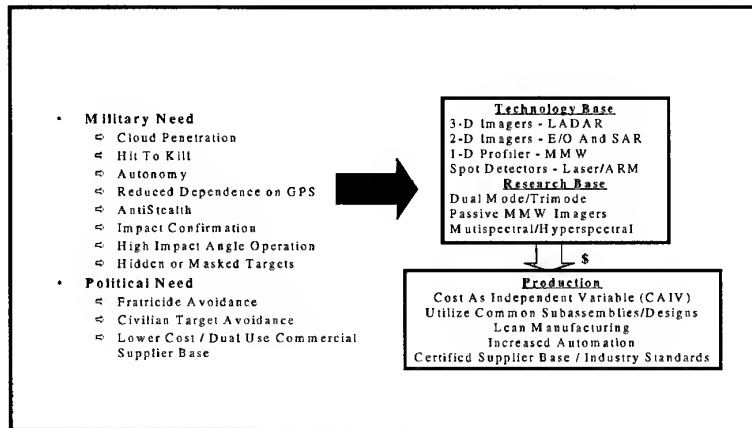

Figure 4 Future Investments

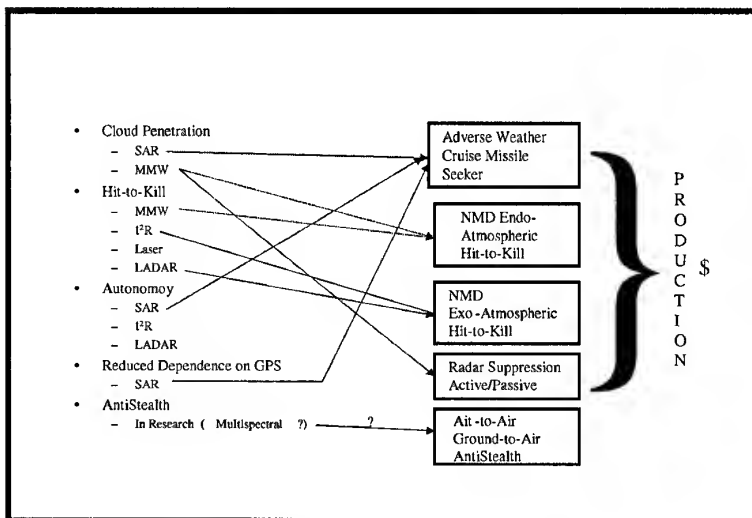

Figure 5 Seeker Versus Mission Area

Figure 6 Cloud Penetration Problem

National Missile Defense (NMD) may have the higher nation priority but it is limited by treaty restrictions. NMD may receive most of the technology investment forcing industry to pick up some of the technology investments required to move new strike warfare seekers into the military inventory. Antistealth by the nature of the difficulty of the problem may remain an unfilled need or approached from directions other than new seekers. Antistealth will be an area for continuous research investments.

Cloud Penetration Problem

Performing the trade studies to select a seeker for a mission where the target area is covered by clouds involves several factors as illustrated by Figures 6. Obviously the sensors ability to see through the clouds is a key factor. As shown at the top of Figure 6, radar seekers have a clear advantage over E/O seekers that are cloud blind. If all targets can be approached at shallow angles such as bridges and industrial buildings, a radar seeker would be a clear winner. Some targets need to be attacked from high approach angles and radars have difficulties once the approach angle gets close to vertical. Near vertical, radar functions more like an altimeter than a traditional radar seeker and range resolution doesn't separate targets from ground clutter. E/O seekers function equally well at high and low depression angles but don't see through the clouds. For these different reasons, both types of seekers are forced to either pop under the clouds and pop up to increase impact angle or just blast through the clouds at a high impact angle. Both approaches have their problems. The SAR can pick an aimpoint at long range and fly inertial to the high impact angle but this stresses the INS to hold the accurate long range fix and drives up the cost of the INS system.

Future Radar Seeker Developments

Many military planners hoped that radar seekers for strike warfare could be fielded in the 1990s and several good attempts were made to achieve this goal such as the MMW Maverick program. For many reasons, this goal must be met in the new millenium. There are three basic technologies that could fill this need and they are called out in Figure 7 as Active & Passive MMW or SAR. Passive MMW using arrays of detectors is still in the early stages of development but progressing quickly. Until a mature producible camera including auto calibration enters the market place it is unlikely that any Passive MMW seeker prototypes will be built. MMW has lost the resolution advantage of being at very high frequencies to SAR seekers that rely on the more affordable approach of high speed computer processing. MMW seekers will need longer detection range which means more transmitter power and more sensitive receivers plus new signal processing techniques to enhance

resolution so it can compete against SAR for a Strike Warfare mission. MMW does retain the advantage that it can see the target at nose on aspects unlike SAR that must look to the side and fly a spiral trajectory and go blind at much longer ranges. If SAR seekers fail to prove that squint mode guidance can achieve high performance, active MMW may appear once again as the leading seeker contender. All active radar seekers must develop processing techniques compatible with high angle attack.

Future of Infrared Seekers

Infrared seekers such as the JASSM seeker, will continue to be important in many Strike Warfare mission areas such as engaging relocatable targets which may often be targets of opportunity because of their minimum exposure time. In the next millenium uncooled infrared seekers will be fielded at a lower cost and with a longer shelf life than cooled seekers. Initially these seekers will fill a need for low performance/low cost seekers but their performance capabilities will grow and they will work their way into mission areas requiring high performance. Cooled detectors will have to offer more than low noise and high resolution. Cooled detector arrays will push for higher yields and greater uniformity to compete with uncooled detectors. Even more important cooled detector arrays are in a better position to offer multiple wavebands and on chip processing. Scene based calibration techniques will also slowly become a standard eliminating the need for expensive infrared calibration reference. The growing competition between uncooled and cooled arrays will accelerate forward improvements in both product areas.

Missile Level Trades

In general seekers are looked at as receiving requirements that are flowed down from the missile level, but when cost is an independent variable, it may be appropriate to trade seeker performance for airframe performance as illustrated in Figure 9. Returning to the cloud penetration problem the

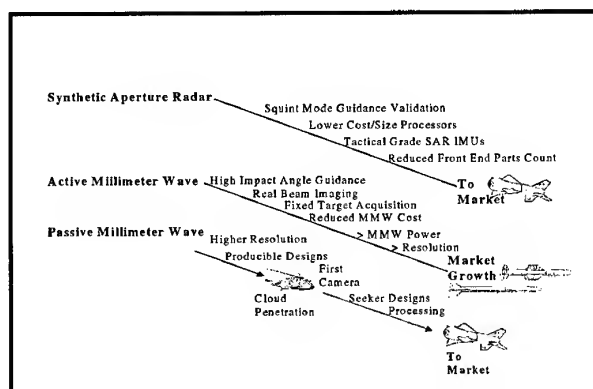

Figure 7 Radar Seeker Developments

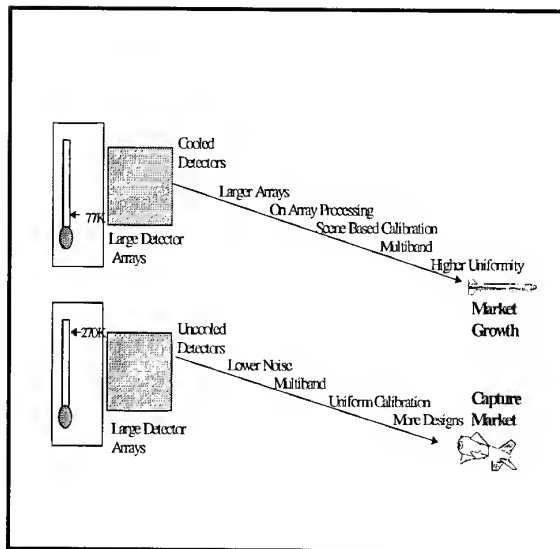

Figure 8 Trends in Infrared Seekers

minimum cloud ceiling that can be handled depends both on the seeker acquisition range and the maneuver capability of the airframe. The higher the airframe maneuverability, the longer the seeker can wait to acquire the target. In the case of moving targets, this directly effects the ability of the missile to stretch in order to catch a target that has moved away from the initial acquisition point. The next millenium may very well see a push for higher performance airframes as a way to reduce seeker requirements, stretch E/O seekers into the cloud penetration scenario or drop the minimum cloud ceiling which increases total number of operational days. Figure 10 shows the amount of airframe maneuverability required as a function of sensor acquisition range and target uncertainty. As sensor acquisition range shrinks because of decreasing cloud cover, the required missile maneuverability increases rapidly. Since the equation is basically $.5at^2$ where a is maneuverability and t is time of flight, maneuverability increases inversely with the square of acquisition range (time of flight is acquisition range divided by missile speed).

Synthetic Aperture Radar Attractive Adverse Weather Seeker

As already stated and shown in Figure 11, SAR is a leading contender for an adverse weather seeker for Strike Warfare. Its ability to provide a high resolution image in all weather at long ranges coupled by computers being the enabling technology make it hard to beat. Millimeter wave seekers that exploit shorter wavelength to achieve better resolution cannot achieve SAR resolution even at moderate ranges. The unanswered questions about SAR is the accuracy that can be achieved using squint mode guidance (missile spirals into the target) and the realizable average unit production prices that can be achieved using the current supplier base for radar components. There is

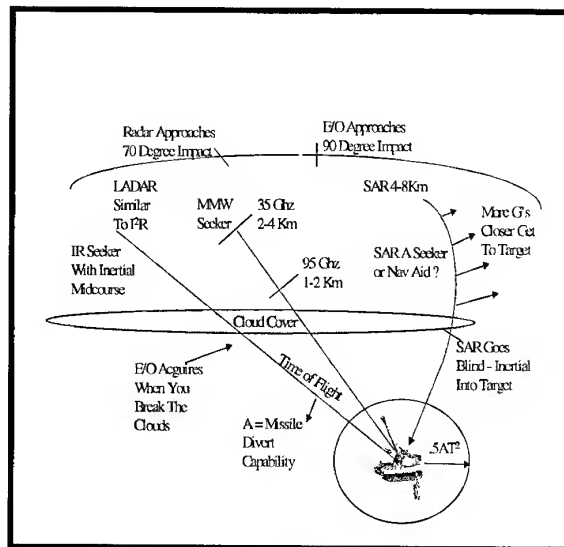

Figure 9 Airframe Seeker Trades

also a question of whether current tactical grade IMUs required to compensate the SAR phase for missile motion are adequate to meet ATR image quality requirements. Once these questions are satisfactorily answered, a SAR production go ahead may be in the near future.

Figure 12 illustrates the subsystems that make up a SAR seeker. In many ways they don't differ from any radar seeker. One of the things that does differ is the quality of the components that are used in the subsystems. The waveform generator needs to be very linear with low phase noise. Fortunately modern missiles have inertial navigation systems which nolong get counted against the cost of the SAR which must have an INS for motion compensation. The biggest difference between a SAR and a MMW radar is the SAR processor since it must handle the complicated image format process and perform complex functions such as a 2-D fast Fourier transform. With modern computers, this is not only very possible in a small, affordable subassembly but it is likely to decrease in price over the life of the SAR seeker production life.

The emerging new Hit-to-Kill technology in the air defense arena, as illustrated in Figure 13, may also find its way to Strike Warfare for similar reasons that make it attractive to the air defense community. Hit to kill means reducing the seeker line of sight measurement error to sufficiently small numbers that the missile hits a lethal aimpoint on the target.

Combining air defense hit to kill technology with ATR may fill an important gap in Strike Warfare reducing collateral damage associated with destroying some weapons of mass destruction, and potentially reducing weapon cost. This will become increasingly possible as the air defense community reduces the price of ownership by maturing the technology, developing a mature supplier base and validating production processes.

Figure 10 Required Missile Maneuverability

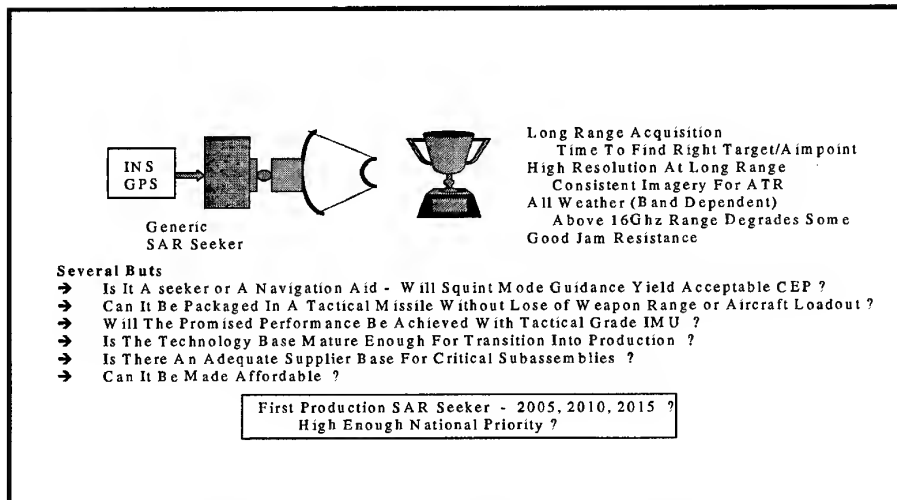

Figure 11 SAR Is Leading Adverse Weather Contender

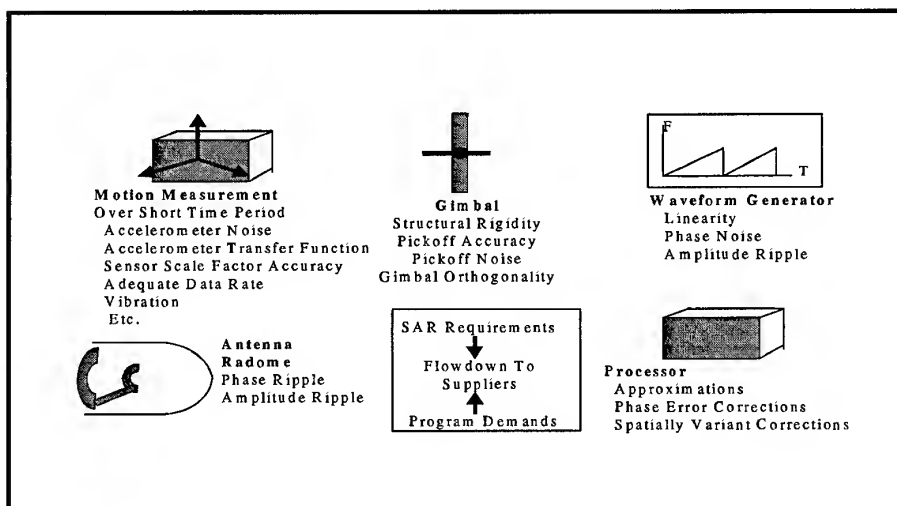

Figure 12 SAR Subsystems

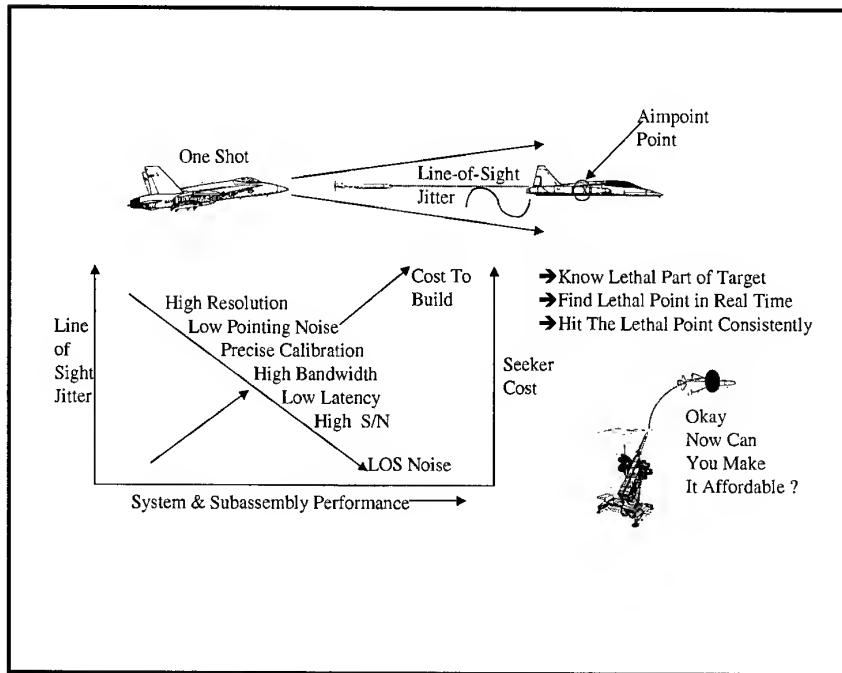

Figure 13 Hit To Kill Technology

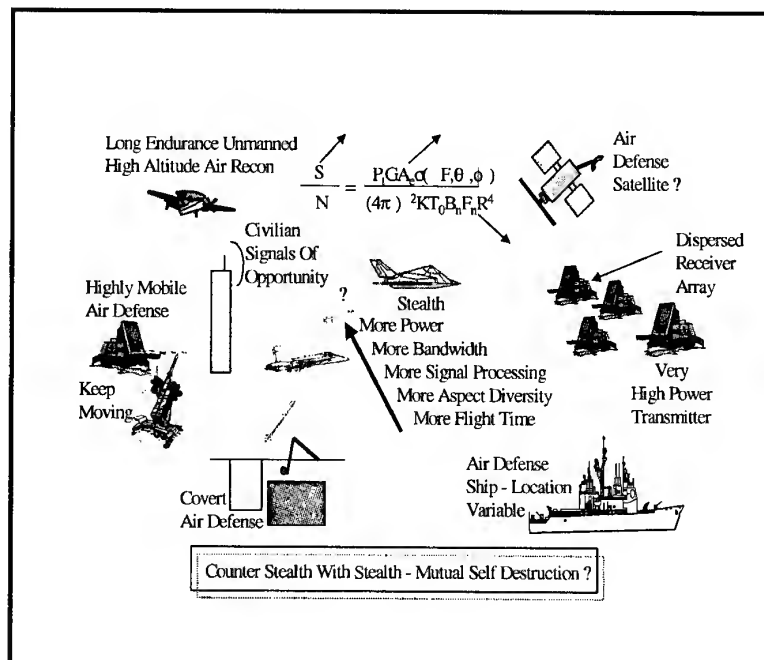

Figure 14 Defeating Stealth

Stealth

Stealth has received so much publicity that it must be considered for two reasons. Strike warfare needs to be aware of what steps the enemy may take to defeat stealth and ground force may develop their own stealth techniques to protect themselves from precision bombing. Some factories have already gone underground becoming stealthy. Relocatable targets hide in holes in the ground for stealth. As Figure 14 states, stealth is associated with the radar range equation. Reduce the radar cross section of the target and the seeker receives less return power. Defeating stealth requires changing another parameter of the radar equation to counter the lower radar cross section. The simplest approach is more transmitted power using high power transmitters. The radar receivers can be made more sensitive or the antennas can be designed for higher gain. The changes that will occur in the future will probably be a mix of these approaches. Strike warfare may be pushed to higher altitudes and may have to attack more concealed targets creating new seeker antistealth requirements.

performance and near total autonomy. The weapons will begin to match the capability of modern aircraft and the needs of the warfighter. The percentage of weapons on target will steadily grow and weapon accuracy will continually improve towards hit-to-kill. In order to protect their warfighting capability, nations will conceal and mask more of their weapon factories, aircraft shelters, munitions storage bunkers creating a stealthy type of environment. This need will be fed by an increase in sophisticated reconnaissance assets making it difficult to hide from strike aircraft. Soon strike warfare will have to respond to a growing ground target stealth problem with more sophisticated sensors and new weapon delivery tactics.

Future Strike Warfare Seekers

The new seekers that will be deployed for strike warfare will be synthetic aperture radar seekers since they are a good match to ATR and are a good fit to INS/GPS midcourse guidance. Initially these seekers will be deployed for fixed targets. As new systems capable of attacking relocatable targets go into production, an infrared sensor will be added to the SAR to track the target all the way to impact. The SAR seeker can track the target through the cloud cover and hand off to the infrared seeker in the terminal flight phase. The infrared seeker will be an uncooled seeker that can perform satisfactorily at short ranges.

In addition to SAR seekers, low cost infrared seekers using uncooled sensors or low cost cooled arrays will be developed for lower cost weapons such as JDAM, JSOW or a Paveway like weapons. These seekers will strive for lowest cost to achieve better than GPS accuracy for increased target kill capability.

Other enhancements to strike warfare seekers will be transmitting the seeker imagery back to an aircraft for target impact assessment and potentially the extraction of intelligence information. As technology develops, goal for weapon CEP will decrease and move towards hit-to-kill type accuracy to reduce collateral damage and destroy hidden targets that might have only small pieces exposed to attack aircraft.

Summary and Conclusions

In summary, the next millenium will be the age of the intelligent missile seekers that will achieve all weather

Technologies for Future Precision Strike Missile Systems - Missile Design Technology

Eugene.Fleeman@asdl.gatech.edu

Abstract/Executive Summary

This paper provides an assessment of the state-of-the-art and design considerations of missile design technology for future precision strike missile systems. Benefits of missile design technology include advanced missile concepts, identification of driving parameters, balanced subsystems, incorporation of new technologies, light weight/low cost missiles, and launch platform compatibility. The paper discusses the missile design process, presents examples of simulation and spreadsheet conceptual design computer programs, provides missile configuration design criteria, and lists references that are applicable to missile design technology.

Missile Design Process

Figure 1 shows the relationship of missile design to the development process of research, technology, and acquisition. Conceptual design is most appropriate during the exploratory development phase of missile development. A primary objective of exploratory development is to investigate and evaluate technology alternatives. The advanced technology development phase of missile development is intended to mature the enabling technologies of key subsystems. Although conceptual design methods are also used during advanced development, preliminary design methods are usually more appropriate. Preliminary design methods continue to be used during the advanced

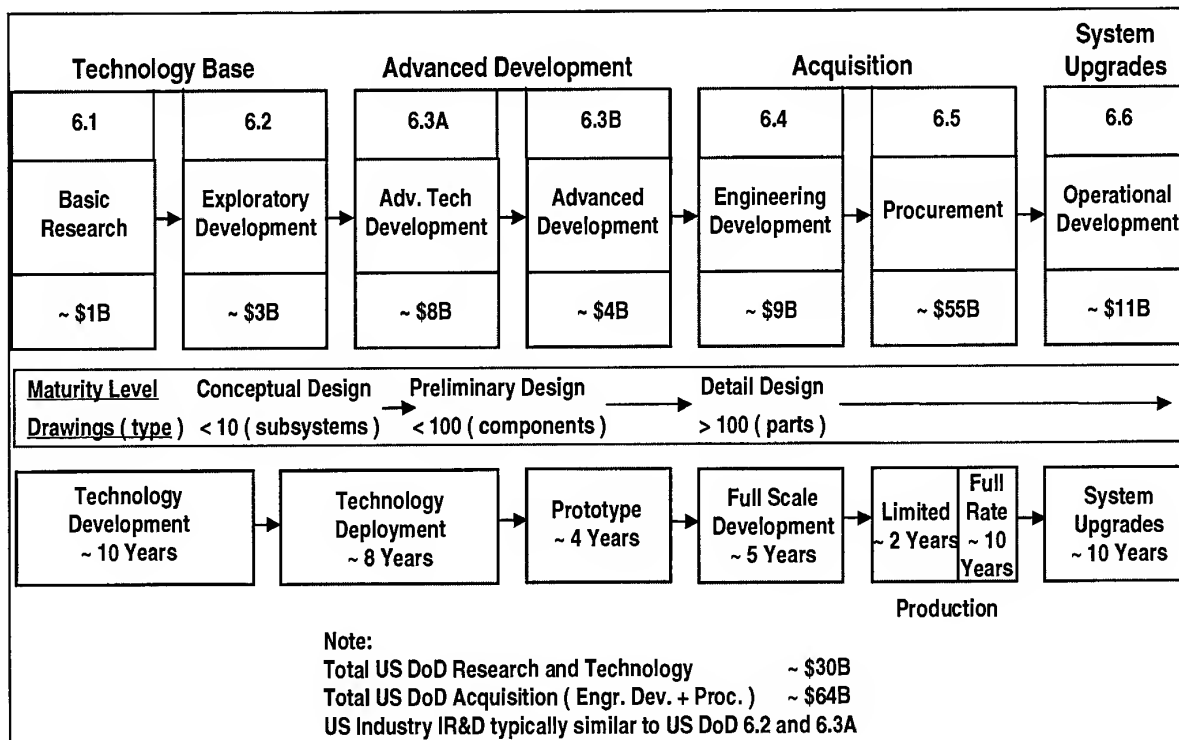

Figure 1. Relationship of Level of Design to the Research, Technology, and Acquisition Process.

development demonstration of the prototype missile. Following successful demonstration of a prototype, the missile program moves into engineering and manufacturing development (EMD). At this point more detail design methods are required.

An indicator of design maturity is the number of drawings that are required to describe the design. Conceptual design may be characterized by fewer than ten drawings, describing fewer than ten subsystems. Conceptual design drawings include the missile overall dimensions, major subsystems layout, and may also list the major subsystems mass properties. Preliminary design drawings of a prototype missile are usually characterized by up to 100 drawings, with greater detail and showing up to 100 components. Preliminary design drawings have fully dimensioned subsystems, inboard layouts showing subsystems, individual subsystem and component drawings, and dimension tolerances. Detail design for EMD usually requires more than 100 drawings and often has more than 1,000 drawings. EMD drawings also have greater detail, including drawings of each part, detailed work assembly instructions and descriptions of the manufacturing processes.

Conceptual design and sensitivity studies should be conducted early in the exploratory development process, and continued into advanced development. Many of the cost performance drivers are locked in during the conceptual design phase. It is therefore important to quickly evaluate a large number of alternatives that cover the feasible design solution space.

Figure 2 shows a typical missile conceptual design process. Conceptual design is an iterative process, requiring a balance of emphasis from diverse inputs and outputs. The major tasks of conceptual design are 1) mission/scenario definition; 2) weapon requirements, trade studies and sensitivity analysis; 3) physical integration of the missile with the launch

platform; 4) weapon concept design synthesis; and 5) technology assessment and technology development roadmap. The initial design process begins with a general definition of the mission/scenario. Mission/scenario definition can have one or more updates during the design process. The initial input is a "requirements pull" desired capability from the military customer. It is evaluated against the "technology push" potential technology availability, provided by the technical community. The weapon requirements, trade studies, and sensitivity analysis task provides high level requirements on the missile such as range, speed, and other measures of merit. This task is oriented towards an operations analysis of a system-of-systems. The high level requirements may be derived from system-of-system models such as campaign, raid, or engagement models. The system-of-systems modeling could include a campaign model with many different types of systems interacting over a simulated time interval from days to weeks. It could also include a raid model of multiple platforms engaging multiple targets. Finally, the system of systems model could include a one-on-one engagement model of a launch platform and missile engaging a target or threat. The third task, physical integration of the missile with the launch platform, provides constraints such as length, span, and weight. This task is oriented towards systems integration. The fourth task, weapon concept design synthesis, is the most iterative and arguably the most creative. As the design matures and becomes more defined through iteration, the number of alternative solutions is reduced from a broad range of possibilities to a smaller set of preferred candidates. More in-depth information is provided for the design subsystems. Finally, a technology assessment task further defines the subsystems and selects the best technology from candidate approaches. The technology trades lead to a set of enabling technologies. A technology roadmap documents the development plan for maturing the enabling technologies.

A typical duration for conceptual design is three to nine months. The products of the missile design activity include refined mission/scenario definitions, system-of-systems definition of the missile requirements, launch platform compatibility, advanced missile concepts, identification of the enabling technologies, and a technology roadmap.

Conceptual design is an opportunity to harmonize diverse inputs early in the development process. The military customer has the lead in providing the "requirements pull" initial input for the mission/scenario definition task. The mission/scenario definition may be modified later as a result of the "technology push" of available capability. The system-of-systems weapon requirements, trade studies, and sensitivity analysis is usually conducted by operations analysis personnel. System integration engineers usually lead the task to integrate the missile with the launch platform. Missile design engineers

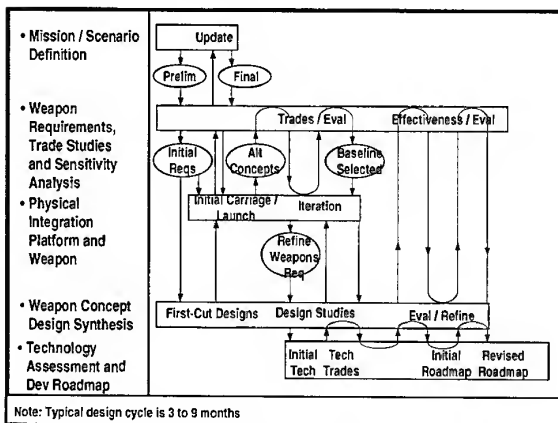

Figure 2. Conceptual Design of Precision Strike Missiles Requires Iteration.

lead the task to synthesize missile concepts. Finally, technical specialists provide the lead input for the "technology push" of potentially available technical capability and the technology development roadmap.

Figure 3 shows current missiles that address the precision strike mission/scenario task shown in the previous figure. The possible solution space for mission/scenario definition of a precision strike missile covers a broad range of alternatives. Precision strike missile targets include fixed targets, radar sites, ships, armor, and buried targets.

In the case of fixed targets (which usually are of large size and relatively soft), a blast fragmentation or dispensed submunition warhead is usually used. These missiles are relatively large, with wings for efficient subsonic flight. Current missiles in this category include AGM-154 JSOW, Apache, KEPD-350, BGM-109 Tomahawk, and AGM-142 Have Nap.

The second target category is radar sites. These are also relatively soft, and a blast fragmentation warhead is usually used. Anti-radar missiles have an anti-radiation homing (ARH) seeker and generally fly at high supersonic Mach number. High speed is desirable for launch aircraft survivability in a SAM

engagement and to minimize the probability of shut down by the threat radar before missile impact. Current anti-radar site missiles include AGM-88 HARM, AS-11 Kilter/Kh-58, ARMAT, AS-12 Kegler/ Kh-27, and ALARM.

A third category is ship targets. Ships are relatively hard targets and usually require a kinetic energy penetrating warhead, followed by blast fragmentation after penetration of the hull. Anti-ship missiles are generally large size and have a large warhead. Anti-ship missiles are designed to survive ship defenses, relying on either speed or flying at low altitude in clutter to survive. Current anti-ship missiles include MM40 Exocet, AS-34 Kormoran, AS-17 Krypton/Kh-34, Sea Eagle, and SS-N-22 Sunburn/3M80.

A fourth category is armor targets. This includes tanks, armored personnel carriers, and other armored combat vehicles. Armor targets are small size, mobile, and very hard. Typical anti-armor warheads include shaped charge, explosively formed penetrator (EFP), and kinetic energy penetrator. Most anti-armor missiles are small size, have hit-to-kill accuracy, and are low cost. The examples shown in Figure 3 are Hellfire/Brimstone, LOCAAS, MGM-140 ATACMS, AGM-65 Maverick, and TRIGAT.

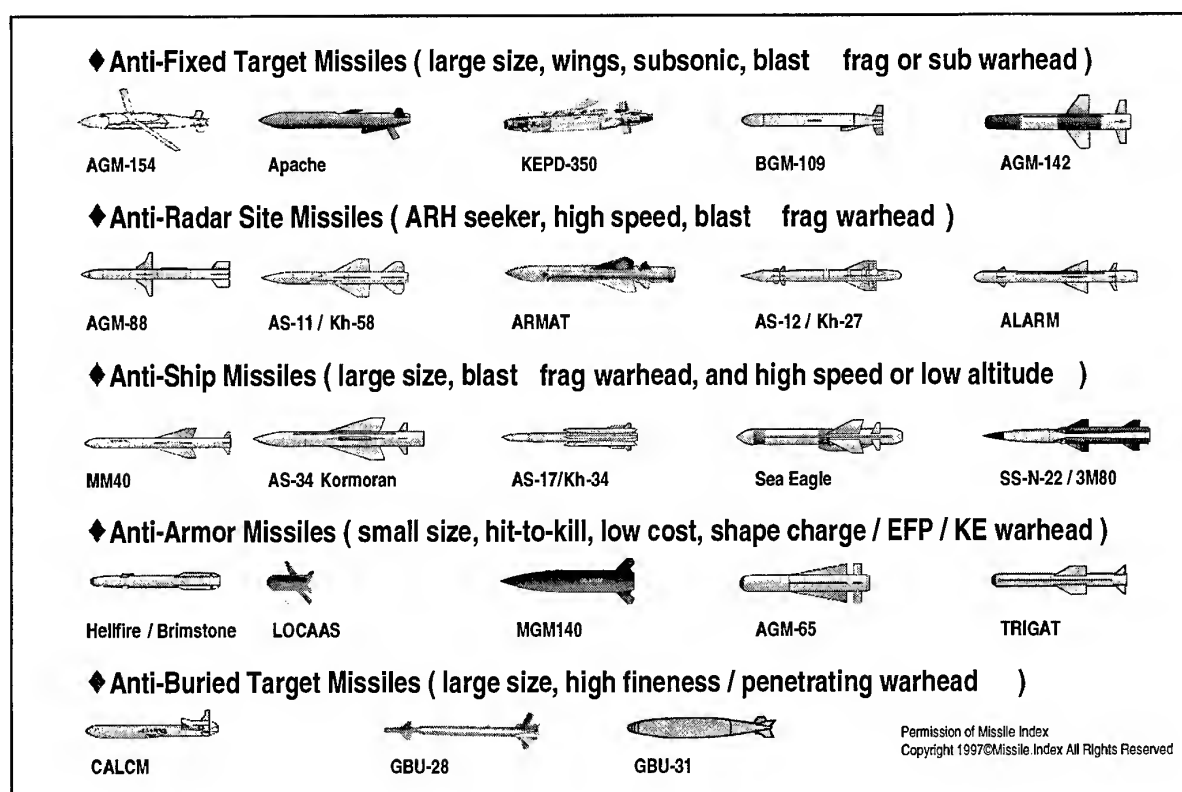

Figure 3. Current Missiles for Precision Strike Mission/Scenario Generally Have Similar Characteristics.

A final category is buried targets, such as underground command posts and bunkers. Buried targets require a high fineness kinetic energy penetration warhead, followed by blast fragmentation. These missiles are large and heavy. Examples of missiles in this category are CALCM, GBU-28, and GBU-31 JDAM.

New precision strike missiles have capability against more than one type of target. An example is a combined capability to engage and defeat hardened, buried targets and mobile surface targets. Benefits of producing a multipurpose missile that is effective against a broader range of targets include reduced unit production cost and reduced logistic cost. A multipurpose precision strike missile requires that the system-of-systems weapon requirements, trade studies, and sensitivity analysis task explore a broad operations analysis space during conceptual design. An example of the broad analysis space for the weapon requirements of future precision strike missiles is shown in Figure 4. One approach is based on a standoff launch platform, with an aircraft or ship standing off outside the threat country border. Hypersonic long-range precision strike missiles provide broad coverage, holding a large portion of the threat country at risk. This approach is attractive in the small number of launch platforms required and the effectiveness against time critical targets. The cost of future hypersonic missiles is expected to be

comparable to that of the current cruise missiles, such as the BGM-109 Tomahawk.

Another alternative approach is to use overhead loitering unmanned combat air vehicles (UCAVs) with hypersonic precision guided missiles. The number of UCAVs required is dependent upon the speed and range of their on-board precision strike missiles. This approach would probably provide the fastest response time against time critical targets, because of the shorter required missile flight range for an overhead loitering system.

A third approach is overhead, loitering UCAVs with subsonic precision guided munitions. This approach would have the lowest cost per shot, but would require a relatively large number of UCAVs.

Figure 5 shows a typical process for conceptual design synthesis. Based on mission requirements, an initial baseline from an existing missile with similar propulsion is established. It is used as a starting point to expedite design convergence. Advantages of a baseline missile include balanced system engineering for the subsystems and an accurate benchmark of test data (e.g., wind tunnel data). Changes in the baseline missile aerodynamics, propulsion, weight, and flight trajectory are then evaluated against the new missile flight performance requirements (e.g., range, time to

Figure 7. Aerodynamic Configuration Sizing Parameters.

shown in Figure 3. In the upper left of Figure 6 is an illustration of a configuration drawing of the baseline missile. The configuration drawing is a dimensioned layout, with an inboard profile showing the major subsystems (guidance, warhead, fuel, booster/engine, and flight control surfaces). In the upper center of the figure are examples of tables for a missile weight statement and geometry data. Missile weight and center-of-gravity location are provided for launch, booster burnout, and engine burnout flight conditions. Weight and geometry data are also provided for the major subsystems. The upper right corner of the figure is an illustration of a description of ramjet internal flow path geometry. The internal flow path geometry data includes the inlet design capture area and the internal areas of the inlet throat, diffuser exit, flame holder plane, combustor exit, nozzle throat, and nozzle exit. Examples of aerodynamic data plots are illustrated in the left center section of the figure. Aerodynamic data for the ramjet baseline covers angles of attack up to 16 degrees and Mach numbers up to 4.0. Aerodynamic coefficients and derivatives include zero-lift drag coefficient (C_{D0}), normal force coefficient (C_N), pitching moment coefficient (C_m), pitching moment coefficient control effectiveness ($C_{m\delta}$), and normal force coefficient control effectiveness ($C_{N\delta}$). Examples of ramjet propulsion thrust (T) and the ramjet specific impulse (I_{sp}) are shown in the center of the figure. Thrust and specific impulse are functions of Mach number and fuel-to-air ratio. Rocket booster propulsion thrust, boost range and burnout Mach number are illustrated in the right center of the figure as a function of launch Mach number and altitude. The left bottom section of the figure shows the maximum flight range of the ramjet baseline. Maximum flight range is a function of launch Mach number and altitude. Finally, the right bottom section of the figure is an example of the sensitivity of design parameters on maximum flight range. Sensitivity parameters include inert weight, fuel weight, zero-lift drag coefficient, lift-curve-slope coefficient ($C_{L\alpha}$), ramjet thrust, and ramjet specific impulse. The sensitivity study in the example was conducted for cruise flight conditions ranging from Mach 2.4/sea level to Mach 3.0/60,000 feet.

Figure 7 is a summary of the aerodynamic configuration sizing parameters for precision strike missiles. Flight condition parameters that are most important are angle of attack, Mach number, and attitude. The missile diameter and length have a first order effect on missile drag, subsystem packaging available volume, launch platform integration, seeker and warhead effectiveness, and body bending. Nose fineness is an important contributor to missile drag, especially for supersonic missiles. Also, nose fineness affects seeker performance, available propellant length, and missile observables. Missile propellant/fuel is directly related to the flight performance range and velocity. Wing geometry and size are often set by maneuverability requirements. Stabilizer geometry and size are often established by static margin requirements. In the flight control area, the geometry and size of the flight control surfaces determine the maximum achievable angle of attack and the resulting maneuverability. Finally, the thrust profile determines the missile velocity time history.

The aerodynamic configuration sizing parameters shown in the previous figure have a strong impact on the weapon requirements for precision strike missiles. Figure 8 is an assessment of the relative impact of aerodynamic configuration sizing parameters on their measures of merit (e.g., weight, range, maneuver footprint, time to target). Also shown is the impact of aerodynamic configuration sizing parameters on other measures of merit (e.g., robustness, lethality, miss distance, observables, survivability, cost), as well as their impact on constraints (e.g., launch platform integration weight, length, and span constraints).

The flight trajectory evaluation activity under missile concept synthesis, discussed previously in Figure 5, requires consideration of the degrees of freedom to be simulated. Figure 9 compares the simulation modeling degrees of freedom that are usually used in conceptual design with the degrees of freedom that are appropriate for preliminary design. As discussed previously, conceptual design requires rapid evaluation of a large range of alternatives, requiring that the design methods be fast, easy to use, and have a broad range of applicability. The simplest model, often acceptable for the conceptual design of high-speed missiles, is one degree of freedom. One degree of freedom modeling requires only the zero-lift drag coefficient, thrust, and weight. Analytical equations can be used to model a one degree of freedom simulation. Other models used for conceptual design are two degrees of freedom, three degrees of freedom point mass modeling, and three degrees of freedom pitch modeling. Finally, missile simulation modeling during preliminary design is usually modeled in six degrees of freedom (6DOF). The 6DOF simulation includes three forces (normal, axial, side), three moments (pitch, roll, yaw), thrust, and weight.

Figure 8. Aerodynamic Configuration Sizing Parameters Have High Impact on Precision Strike Missile Measures of Merit and Constraints.

It is instructive to examine the equations of motion for missile design drivers. Figure 10 shows the equations of motion for three degrees of freedom with pitch modeling. The figure shows the missile angular acceleration ($\ddot{\theta}$), rate of change in the flight path angle ($\dot{\gamma}$), and the rate of change in the velocity (\dot{V}). The configuration sizing implication from examining the angular acceleration equation shows the importance of control effectiveness. High control effectiveness is provided by high pitching moment control effectiveness ($C_{m\delta}$), low static stability ($C_{m\alpha}$), and small moment of inertia (I_y). A small moment of inertia is a characteristic of a light weight missile. The second equation shows the design drivers for missile maneuverability. High maneuverability is the capability to make large and rapid changes in the flight

path angle. This occurs for large normal force coefficient (C_N), light weight (W), and low velocity (V). Implications of the third equation are missile speed and range. High-speed and long-range flight is provided by large total impulse, or the integral of thrust for the burn time duration ($\int T dt$). There is payoff for flight range in using high density propellant/fuel. High density propellant/fuel increases the total impulse of a volume limited propulsion system. The third equation also shows that low axial force coefficient (C_A) provides longer range. Axial force coefficient is approximately equal to zero-lift drag coefficient (C_{D0}).

Referring back to Figure 2, the physical integration of the conceptual missile with the launch platform uses first-cut missile designs for an initial check on carriage

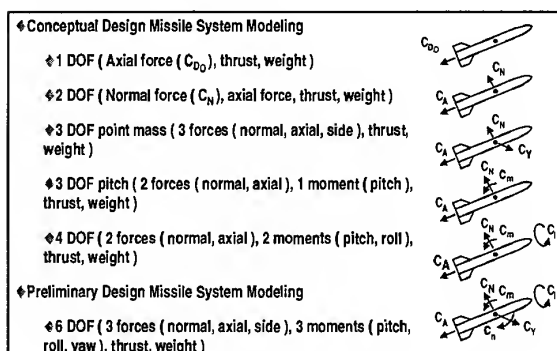

Figure 9. Conceptual Design Uses Simple Modeling of the Missile System.

Figure 10. 3DOF Simplified Equations of Motion Show Drivers for Missile Configuration Sizing.

Figure 11. Missile Shape, Size, and Weight Are Driven By Launch Platform Compatibility.

and launch compatibility. Additional checks in launch platform compatibility are made during the design iteration process. Examples of launch platform carriage constraints for missiles on surface ships, submarines, and aircraft are shown in Figure 11. In the United States, the Vertical Launch System (VLS) is a standard carriage and launch system for missiles on surface ships. The VLS geometry constraints are 22 in x 22 in x 256 in. The maximum weight constraint is 3400 lb. United States submarines have a similar standard launcher that is circular in cross section. The submarine Canister Launch System (CLS) has a diameter constraint of 22 inches and a length constraint of 256 inches. Maximum missile weight for the CLS is the same as VLS, 3400 lb. Finally, aircraft launch platforms for precision strike missiles include tactical fighters, bombers, and helicopters. Shown in the figure is an example of a fighter aircraft, the F-18C. The F-18C carries weapons externally on pylons and rails. Other aircraft, such as the F-22, have an additional capability of internal carriage. Missile span constraint for aircraft is about 24 in x 24 in. Length constraint is about 168 in, and maximum missile weight varies from about 1,000 to 3,000 lb, depending upon the aircraft. There is a strong desire for light weight precision strike missiles, in order to maximize the firepower of small aircraft, such as the F-18C.

Finally, referring back a final time to Figure 2, note that the last activity in conceptual design is technology assessment and a technology development roadmap. Technology road maps identify the technology drivers, key decision points, critical paths, and resource needs. The purpose of a technology roadmap is to establish time phase relationships for the missile technology development activity. This includes 1) development of plans for technology development and validation, 2) identification of technology options, 3) setting time-phased technology goals, and 4) development of a plan for technology transition. The technology plan shows a proposed approach in maturing the missile through the missile development phases previously discussed in Figure 1. As a result of technology development, the missile level of maturity will move from that of exploratory development, to advanced technology

development, to a prototype demonstration. For most new missiles, a technology development, risk reduction, and maturity demonstration activity is required prior to entering EMD.

Examples of Missile Conceptual Design Simulation Programs

A fundamental requirement for conceptual design is short turnaround time. Fast turnaround time is necessary to search a broad solution space with a sufficient number of iterations for design convergence. The computer program used in conceptual design should be fast and easy to use. A good design code connects the missile physical parameters directly to a trajectory code that calculates flight performance.

More detailed computational methods are used later, in preliminary design, when the number of alternative geometric, subsystem, and flight parameters has been reduced to a smaller set of alternatives. As an example, it is inappropriate to use computational fluid dynamics (CFD) in conceptual design. The mathematical considerations of CFD (e.g., mesh size, time interval, numerical stability, turbulence modeling, smoothing) are impediments to the fast response required for conceptual design. Similarly, a 6DOF trajectory simulation is inappropriate for convenient evaluation of missile guided flight. The development of the required autopilot for 6DOF guided flight is time consuming, diverting emphasis from other more appropriate considerations. Similarly, missile optimization codes are generally inappropriate for conceptual design. Optimization in conceptual design is best left to the creativity and the intuition of the designer. Also, optimization codes work best when there is a continuous smooth variation in parameters, which is usually not the case in conceptual design. For example, optimization codes do not work well in comparing ramjet propulsion versus rocket propulsion. The CFD, 6DOF guided flight trajectory simulations, and optimization codes have seductive "precision." However more often than not their accuracy in conceptual design is worse than simpler methods. Simpler aerodynamic and simulation methods, combined with a well defined baseline missile, and the designer's creativity and intuition are a preferable approach for alternatives selection, sizing, and optimization. They are invariably more accurate and robust. References 1 through 4 are examples of conceptual design methods that are fast, robust, and have sufficient accuracy for the relative screening of missile concept alternatives.

A synthesized missile will differ from the starting point baseline in several respects. For example, the wing area may be resized to meet the maneuverability requirement. The tail area may be resized to meet static margin and maximum trim angle of attack requirements. The rocket motor or the ramjet engine may be modified to improve its efficiency at the selected design altitude. Additionally, the length of

the propulsion system may be changed in order to accommodate additional propellant/fuel necessary to satisfy flight range requirements. The design changes are reflected in revisions to the mass properties, configuration geometry, thrust profile, and flight trajectory for the missile. Typically, three to ten design iterations are required before a synthesized missile converges to meet the flight performance requirements.

Advanced Design of Aerodynamic Missiles (ADAM). The following discussion of the ADAM missile simulation program (Reference 4) is provided as an example of a computer program that meets the conceptual design criteria of speed, ease of use, and applicable to a broad range of configurations and flight conditions. ADAM is a DOS code that runs on a PC. The aerodynamics predictions are based on the slender body and linear wing theory of Reference 5. Except at Mach 1, the aerodynamic methods are valid from subsonic through hypersonic Mach numbers. The ADAM aerodynamics module calculates static stability derivatives, dynamic stability derivatives, trim conditions, and control effectiveness. Modeling of the equations of motion can be in three, four, five, or even six degrees of freedom. The three degrees of freedom flight trajectory model requires approximately one second of run time on a PC. The 6DOF flight trajectory simulation is used to analyze the nutation/precession modes of missiles during their unguided portion of flight, unguided bombs, and unguided projectiles. It requires approximately three seconds of run time on a PC. For homing missiles, proportional guidance is used, as well as other guidance laws. The input to the flight trajectory module is provided automatically by the aerodynamics module, simplifying the user input. The benchmark missiles used in the aerodynamics module have corrected coefficients and derivatives based on wind tunnel data. Greater than fifty input parameters are available. The input default is the baseline missile parameters, simplifying the input data preparation.

The baseline missiles in ADAM include air-to-air, surface-to-air, air-to-surface, and surface-to-surface missiles. The aerodynamic modeling of the body includes the diameter, nose configuration (geometry, fineness, bluntness), body bulge, boattail, and length. Up to three surfaces (stabilizers, wings, and controls) can be specified. The geometric modeling of each surface includes: the location, leading edge root and tip station, span, trailing edge root and tip station, thickness, control surface deflection limit, and the number of surfaces. The program models the missile center of gravity variation from launch to burnout. For propulsion, the thrust is modeled as a two value thrust profile, of a given time duration. The propellant weight of each thrust-time phase can also be specified. The target can be fixed or moving. Down range and cross range of the target is specified, as well as target altitude and velocity. Launch conditions for the missile are specified, including altitude, velocity,

launch angle, and the guidance law. The output of a three degrees of freedom pitch simulation modeling includes a drawing of the missile geometry with dimensions, aerodynamic coefficients and derivatives, flight performance parameters (velocity, trim angle of attack, acceleration, range, trim control surface deflection) versus time, and missile miss distance.

Tactical Missile Design (TMD) Spreadsheet.

Another computer technique suitable for conceptual design is spreadsheet analysis. Figure 12 (following page) shows the design parameters of the TMD Spreadsheet (Reference 1). The TMD Spreadsheet runs in Windows on a PC. It has six modules that follow the conceptual missile design tasks outlined in Figure 5. Based on external mission requirements (e.g., maximum range, minimum range, average velocity, measures of merit, and constraints), a baseline design is selected from the baseline missile spreadsheet module. Currently there are two possible baselines: a rocket powered missile, similar to the Sparrow AIM-7 missile, and a ramjet missile. The configuration, subsystem, and flight performance characteristics of the ramjet missile baseline are illustrated in Figure 6. The rocket missile baseline has a similar level of detail in its configuration, subsystem, and flight performance data.

Following the definition of mission requirements and the selection of a baseline configuration in the baseline spreadsheet module, the aerodynamics spreadsheet module is exercised. The aerodynamics spreadsheet module calculates zero-lift drag coefficient, normal force coefficient, aerodynamic center location, pitching moment control effectiveness, lift-to-drag ratio, and the required tail stabilizer surface area. The output data from the aerodynamics spreadsheet module, along with other default data from the baseline missile, are input into a propulsion spreadsheet module. The methodology used to calculate the aerodynamics of a supersonic missile body are based on slender body theory (Reference 5) for the linear low angle of attack contribution and blended with cross flow theory (Reference 6) at high angles of attack. It is applicable for all angles of attack, from zero to 180 degrees. The method used in calculating aerodynamics of supersonic missile fixed surfaces (e.g., wings, strakes, stabilizers) and movable surfaces (e.g., canards, tails) is based on linear wing theory (Reference 5) at low angle of attack and blended with Newtonian impact theory (Reference 6) at high angles of attack. The methods are valid for Mach numbers greater than about 1.5.

The propulsion spreadsheet module provides an estimate of range, velocity, thrust, and specific impulse. For a ramjet, the output also includes total pressure recovery in the inlet (Reference 7). Rocket motor thrust and specific impulse are based on the isentropic flow equations, adjusted for the change in specific heat ratio with temperature. Incremental velocity and range are based on the one-degree of

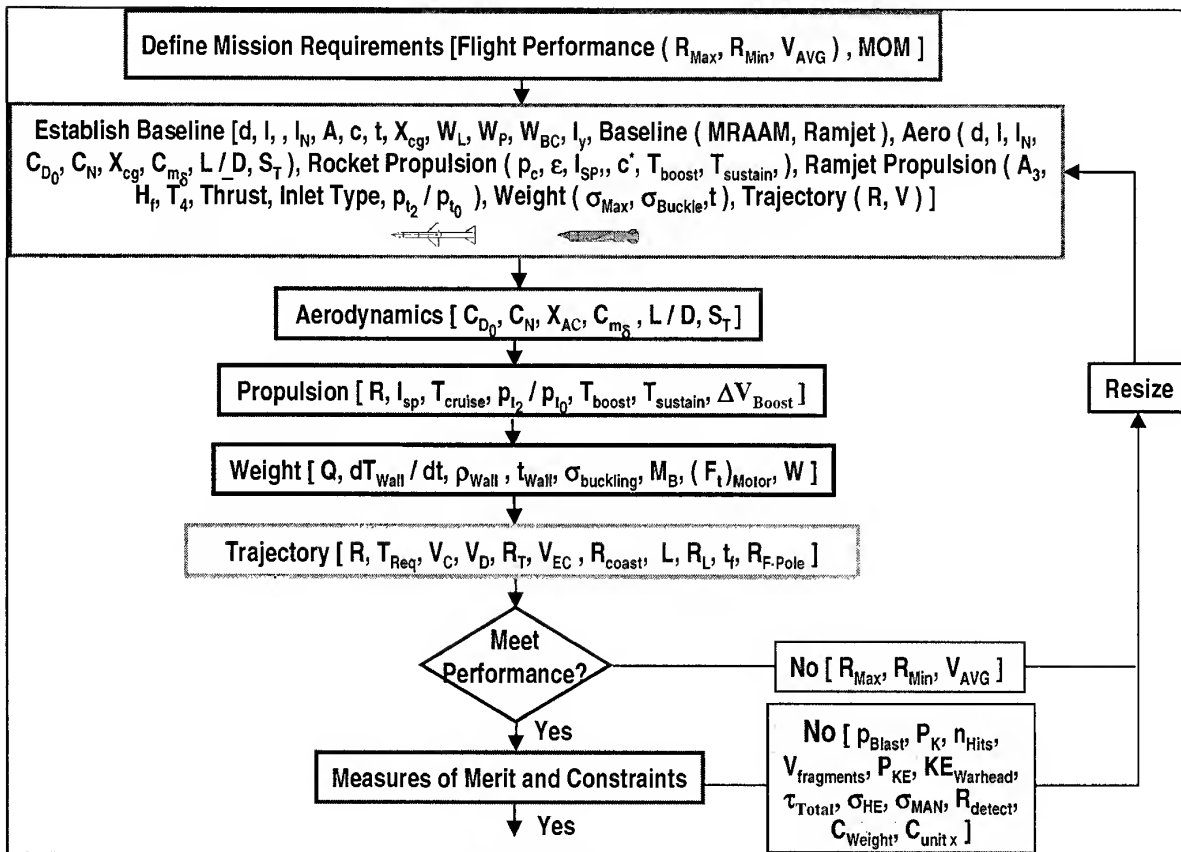

Figure 12. Tactical Missile Design (TMD) Spreadsheet Parameters.

freedom equation of motion. The ramjet thrust and specific impulse predictions include the forebody and cowl oblique shocks and the inlet normal shock losses in total pressure.

After redesigning the aerodynamic configuration and propulsion system, a weight spreadsheet is used to revise the missile weight. The weight spreadsheet module includes an estimate of aerodynamic heating, surface temperature versus time, required airframe and motor case thickness, buckling stress, bending moment, motor case stress, and the density/weight of subsystems. Missile system weight scaling is provided by the density relationship with diameter described in Reference 8. Scaling of the weights of subsystems is provided by the density relationships in Reference 1. Material data (e.g., density, stress-strain versus temperature) are also from Reference 1. Predictions of aerodynamic heating and surface temperature rate are given by the method described in Reference 9. Finally, missile body buckling stresses due to bending moment and axial loads, motor case stress, and required motor case thickness are from Reference 1.

The flight trajectory spreadsheet module has analytical expressions for one degree and two degrees of freedom trajectories. The output includes flight range, thrust required for steady flight, steady climb velocity,

steady dive velocity, turn radius, velocity at the end of coast, range at the end of coast, seeker lead angle for proportional homing guidance, required launch range, missile time of flight, and F-pole range. Flight trajectory methods are based on closed-form analytical methods. Cruise range prediction is based on the Breguet range equation described in Reference 1. Thrust required for steady cruise, steady climb, and steady dive is based on Reference 10. Turn radius, coast velocity, coast range, missile homing lead angle, launch range, and F-pole range (relative range between the launch platform and the target when the missile impacts the target) are based on Reference 1.

Finally, the designer compares the output of the flight trajectory spreadsheet module against mission flight performance requirements. If the missile design does not meet the flight performance requirements, the process is repeated until the requirements are satisfied. The modularity of the spreadsheet and the default baseline missile data allows the designer to easily modify the input for the next iteration.

Once flight performance requirements are met, the measures of merit and constraints are then evaluated. The measures of merit spreadsheet module calculates parameters for warhead lethality, miss distance, survivability, and cost. Output parameters for the warhead lethality measure of merit include warhead

blast pressure, kill probability, number of warhead fragments impacting the target, warhead fragment velocity, kinetic energy warhead penetration, and missile kinetic energy impacting the target for hit-to-kill missiles. Warhead blast pressure is based on Reference 11. Fragment velocity, kill probability, number of warhead fragments impacting the target, kinetic energy warhead penetration, and penetrator kinetic energy are based on Reference 1. Kinetic energy penetration depth is based on Reference 12. Output parameters for the missile miss distance measure of merit include missile time constant, missile miss distance due to heading error, and missile miss distance due to a maneuvering target. Miss distance is based on References 1 and 13. Output parameters for the missile survivability measure of merit include detection range, based on Reference 1. Finally, the output parameters for missile cost measure of merit include missile production cost due to weight and missile production cost due to the learning curve. Cost prediction is based on Reference 1, using data from Reference 14.

Again, the missile design is iterated until the measures of merit and constraints (such as launch platform integration) are satisfied.

Configuration Conceptual Design Sizing Criteria

An examination of configuration characteristics of the current precision strike missiles, missile sizing method parameters, and missile design activities suggests configuration design criteria. Table 1 has eleven configuration design criteria related to flight performance and guidance & control.

Configuration design criteria related to flight performance include missile body fineness ratio, nose fineness ratio, boattail ratio, cruise dynamic pressure, ramjet combustor temperature, and inlet integration. A design criterion for the missile body fineness ratio (length-to-diameter ratio) is that it should be between 5 and 25, to harmonize tradeoffs of drag, subsystem

packaging available volume, launch platform integration, seeker and warhead effectiveness, and body bending. The nose fineness (nose length-to-diameter ratio) for supersonic missiles should be greater than 1 to avoid high drag at high speed. Boattail ratio (boattail diameter-to-maximum missile diameter ratio) should be greater than 0.6 for supersonic missiles to avoid increased drag at high speed. A design criterion for efficient cruise flight is that the dynamic pressure be less than 1,000 lb/ft². Ramjet combustor temperature should be greater than 3,500 degrees Fahrenheit for high specific impulse and thrust at Mach number greater than 3.5. Efficient inlet integration for supersonic missiles requires at least one oblique shock prior to the inlet normal shock, for good inlet total pressure recovery at Mach numbers greater than 3.0. For Mach numbers greater than 3.5, at least two oblique shocks prior to the inlet normal shock are desirable for inlet total pressure recovery.

Configuration design criteria related to guidance & control include the flight control actuator frequency, trim control power, stability & control derivatives cross coupling, airframe time constant, and proportional guidance ratio. Body bending frequency in the first mode of aeroelasticity should be greater than 2X the flight control actuator frequency if possible, to avoid the complication and risk of notch filters. Trim control power (trim angle of attack-to-control surface deflection ratio) should be greater than 1 for maneuverability. Stability & control derivatives cross coupling should be less than 30% for efficient dynamics. The missile airframe time constant should be less than 0.2 seconds for precision accuracy (3 meters). Contributors to a low value of the airframe time constant include high maneuverability capability, neutral static margin, high rate control surface actuators, low dome error slope, and a low noise seeker. Proportional guidance ratio should be between 3 and 5 to minimize miss distance. Values less than 3 result in excessive time to correct heading error, while values greater than 5 make the missile overly sensitive to noise input from the seeker.

Summary/Conclusions

Missile design is a creative and iterative process that includes system considerations, missile sizing, and flight trajectory evaluation. Because many of the cost and performance drivers are "locked in" early during the design process, the emphasis of this paper has been on conceptual design.

Conceptual design is an opportunity to harmonize diverse inputs early in the missile development process. The military customer, operations analysts, system integration engineers, conceptual design engineers, technical specialists, and others work together in harmonizing the mission/scenario definition, system-of-system requirements, launch platform integration, missile concept synthesis, and technology assessment/roadmaps.

Configuration Sizing Parameter	Design Criteria
◆ Flight Performance Related	
◆ Body fineness ratio	$5 < l/d < 25$
◆ Nose fineness ratio	$l_n/d > 1$ if $M > 1$
◆ Boattail ratio	$0.6 < d_b/d_{max} < 1.0$
◆ Cruise dynamic pressure	$q < 1,000$ psi
◆ Ramjet combustor temperature	$> 3,500$ Degrees Fahrenheit
◆ Ramjet inlet integration	> 1 oblique shock if $M > 3.0$, > 2 oblique shocks if $M > 3.5$
◆ Guidance & Control Related	
◆ Body bending frequency	$\omega_{bb} > 2\omega_{act}$
◆ Trim control power	$\alpha/\delta > 1$
◆ Stability & control cross coupling	$< 30\%$
◆ Airframe time constant	$\tau < 0.2$ sec
◆ Proportional guidance ratio	$3 < N < 5$

Table 1. Precision Strike Missile Configuration Design Criteria.

Missile conceptual design is a highly integrated process requiring synergistic compromise and tradeoffs of many parameters. The synthesis of an effective compromise requires balanced emphasis in subsystems, unbiased tradeoffs, and evaluation of many alternatives. It is important to keep track of assumptions to maintain traceable results. Starting with a well-defined baseline which has similar performance and propulsion expedites design convergence and provides a more accurate design.

Conceptual design is an open-ended problem and has no single right answer. The available starting point information is never sufficient to provide only one solution. The design engineer makes assumptions in coming up with candidate concepts, subsystems, and technologies to satisfy mission requirements and cover the solution space. Weighting of the most important measures of merit is required in coming up with a cost-effective solution. Trade studies are conducted to investigate the impact of design parameters. Sensitivity analyses are also conducted to evaluate the effects of uncertainty in the design and the benefit of new technology. The missile is designed for robustness to handle risk and uncertainty of both a deterministic and a stochastic nature.

A good conceptual design code connects the missile geometric, physical, and subsystem performance parameters directly into a flight trajectory evaluation. Good conceptual design codes do not automatically change the design or resize automatically. It is best that the missile designer make the creative decisions.

Technologies for Future Precision Strike Missile Systems - Missile/Aircraft Integration

Eugene L. Fleeman
Aerospace Systems Design Laboratory
School of Aerospace Engineering
Georgia Institute of Technology
Atlanta, Georgia 30332-0150, United States
Eugene.Fleeman@asdl.gatech.edu

Abstract/Executive Summary

This paper provides an assessment of the state-of-the-art and design considerations of missile/aircraft integration for future precision strike missile systems. Benefits of missile/aircraft integration include compatibility with a broader range of aircraft carriage platforms, unrestricted carriage envelope, safe and accurate store separation, and enhanced survivability for the aircraft platform. Technologies and design considerations are grouped into the following discussion areas:

- **Missile factor of safety compatibility.** Assessments in this area include structural design factor of safety, carriage flight loads, and design specification of the carriage flight environment.
- **Missile carriage and launch compatibility.** Assessments in this area include launch platform compatibility constraints, firepower, launcher alternatives, compressed carriage, and standard suspension requirements.
- **Survivability (missile observables/insensitive munitions) compatibility.** Assessments in this area include internal carriage, reduced observable plumes, and insensitive munitions.

Introduction

Missile/aircraft integration is an important part of the missile design process, as illustrated in Figure 1. Launch platform integration sets constraints on the missile that must be considered early in the development process. Moreover, the design process requires iteration to harmonize the outputs from the diverse areas of mission/scenario definitions, missile requirements, aircraft integration, missile concepts, and technologies. In a few cases it may be possible to modify a launch platform to accommodate a new missile, but in most cases this is not an option. Generally the launch platform is a constraint that drives the missile design. For example, AMRAAM was modified to a compressed carriage configuration (clipped wings and tails) to better accommodate internal carriage in the F-22 center weapons bay.

Precision strike missiles are driven as much by launch platform compatibility as other measures of merit.

Figure 2 shows an example of the design validation/technology development process. Launch platform integration is considered from the start of subsystem development activities, continuing as they evolve into a missile system. In the propulsion area, static firings and insensitive munition tests are conducted before a missile with a live rocket motor is fired from a launch aircraft. In the airframe area, wind tunnel testing includes not only the basic aerodynamic configuration development, but also store separation wind tunnel tests. In the guidance & control area, the flight control system sensors, actuators, and electronics are analyzed to ensure safe separation as part of a missile modeling and simulation activity. Similar to the propulsion area, the warhead has insensitive munition tests prior to firing a missile with a live warhead from an aircraft.

The flight test progression is shown on the far right of Figure 2. Flight test validation is a progressive activity of increasing complexity. The objective of progressive testing is to minimize risk and enhance safety in the flight test activity. A typical progression of flight testing begins with captive carry and ends with live warhead launches. Intermediate tests are store jettison tests, safe separation tests, unpowered guided flights with an inert warhead, powered guided flights with an inert warhead, and finally, all-up powered guided flights with a live warhead.

A summary of the subsystem technologies for precision strike missiles that relate to missile/aircraft integration is given in Figure 3. In addition to subsystem technologies, considerations such as structure design, carriage environment, geometry/weight constraints of the aircraft, aircraft launcher requirements, and aircraft survivability also drive missile/aircraft integration. Many of the technologies in the figure are covered in this paper, however there is not sufficient time to address them all. A summary of other technologies is presented in the Introduction/Overview paper of this lecture series.

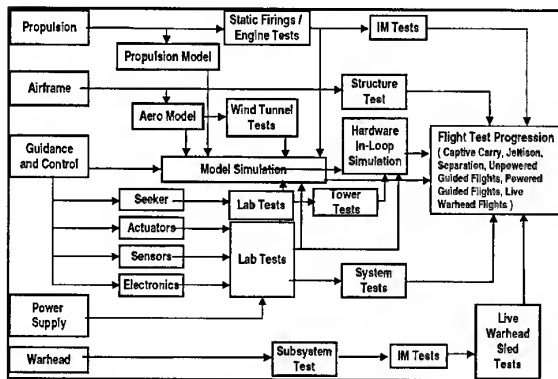

Figure 2. Air Launched Precision Strike Missile Development Leads to Aircraft Flight Test Validation

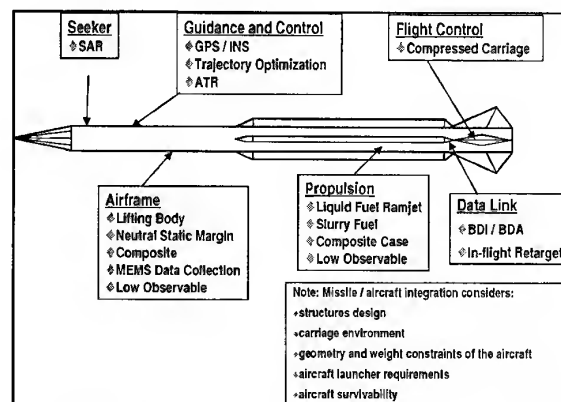

Figure 3. New Precision Strike Missile Technologies That Impact Aircraft Integration.

Missile Factor of Safety Compatibility

This assessment of missile factor of safety compatibility addresses the design considerations of structural design factor of safety, process for defining the missile structure design for compatibility with carriage flight loads, and design specification of the carriage flight environment.

Structural design factor of safety. Missile structure/aircraft integration includes the factor of safety considerations for manned operation. Typical factors of safety for tactical missiles are shown in Figure 4. The factor of safety tends to be high where there is human danger involved. As an example, pressure bottle ultimate and yield factors as safety are typically 2.5 and 1.5 respectively. Missile gas bottles

can be pressurized up to 10,000 psi. Because gas bottles require periodic logistics maintenance and inspection by ground personnel, the factor of safety is high. Another area where the factor safety is high is in the area of ground handling loads, such as cross-country transportation. Factors of safety for ground handling loads are 1.5 ultimate loads and 1.15 in yield loads. Other examples of high factor of safety are captive carriage and separation. During carriage or during aircraft separation, missile factors of safety are required to be about 1.5 ultimate and 1.15 yield. The motor case is designed not only for conditions of environmental extremes, such as a hot day, but also for consideration of pilot safety. The ultimate and yield factors of safety for motor maximum effective operating pressure are about 1.4 and 1.1 respectively. The required factors of safety are lower for flight conditions where the missile is safely away from the launch aircraft. For example, missile free flight loads factors of safety are about 1.25 and 1.1 respectively and the thermal loads, which occur near the end of flight, are just design considerations with a factor of safety of 1.0. A distinguishing characteristic of precision strike missiles is lower factor of safety compared to manned aircraft or even unmanned air vehicles (UAVs). Since missiles are a throw-away, the factor of safety can be reduced if there is no human danger involved, resulting in lighter weight compared to an aircraft or a UAV. It is noted that an additional factor of safety is required for structural areas where there is relatively large uncertainty. An example is castings, which can have hidden voids, requiring an incremental factor of safety of about 1.25 in addition to the normal design factors of safety. Fittings also require an additional factor of safety of about 1.15 because of the uncertainty in the analysis for attachment integrity. The applicable military standards, in the U.S. that are considered in factors of safety include environmental military standards such as MIL-STD-210 and 810, strength and rigidity standards such as MIL-STD-8856, and the carriage requirements of MIL-STD-8591.

Because high performance missiles such as ramjets are severely weight and volume limited, there is high leverage in improving performance if the required factor of safety could be reduced. Technology in improved analysis and development tools will provide

Figure 4. Missile Structural Design Is Driven by Safety.

reductions in missile weight and cost by reducing the design uncertainty and the required factor of safety. An example is Micro-machined Electro-Mechanical Systems (MEMS) technology. MEMS devices are fabricated from a single piece of silicon by semiconductor manufacturing processes, resulting in a small, low-cost package. For example, between 2,000 and 5,000 MEMS sensor devices are produced from a single five-inch silicon wafer. Future precision strike missiles will have low cost/small size MEMS sensors for data collection during missile development and for health monitoring after production. Localized stress/strain, vibration, acoustics, temperature, pressure, and other environmental conditions can be monitored through many sensors scattered around the airframe.

Carriage flight loads. Figure 5 shows the considerations of flight carriage on missile design. A comparison is shown of a representative distribution of missile free flight maneuver loads versus carriage loads. The figure shows a typical weight load distribution on each bulkhead, air loads, and carriage loads. As shown in the figure, carriage loads are taken out through a suspension system. It is usually possible to get a fairly accurate prediction of the missile free flight loads. Also, wind tunnel tests are usually conducted to determine free flight air loads. Unfortunately, this is usually not the case for carriage flight loads, as it is difficult to accurately predict the two-body problem of a store in the flow field of the launch aircraft. In addition, it is difficult to get accurate wind tunnel data, due to the small size of the missile model for aircraft carriage wind tunnel tests. As a result, the current process for estimating carriage loads is usually based on the conservative process of MIL-STD-8591. As missile loads estimation becomes more accurate in the future, there is a potential for structure weight savings, based on improving the estimation accuracy for captive carriage loads.

Design specification of the carriage flight environment. Air launched precision strike missiles

Figure 5. Process for Captive and Free Flight Loads Calculation.

Environmental Parameter	Example of Environmental Requirement
Temperature	-50° F to 160° F
Humidity	5% to 100%
Rain	4.0 mm / hr to 120 mm / hr
Snow	Crystal size 0.05 to 20.0 mm 21mm / hr snow rate
Wind	54 m / s gusts
Salt fog	3 grams / mm ² per year
Vibration	MIL STD 810, MIL STD 648
Shock	Drop height 0.5 m MIL STD 810 100 g's 10 ms, half sine wave Drop height 0.5m MIL 810
Acoustic	160 dB

Table 1. Robustness Is Required to Satisfy Aircraft Carriage Environmental Requirements.

must have sufficient robustness in their design to accommodate a broad flight environment during carriage. Table 1 has examples of environmental requirements for aircraft carriage temperature, humidity, rain, snow, wind, salt fog, vibration, shock, and acoustics. An example of concern at the temperature extremes is propulsion and warhead safety, reliability, and performance. Another example is high rain rate. Rain is a particular concern for dome erosion at high carriage velocity. A third example is corrosion from salt fog, particularly for naval operation. An advantage of internal bay carriage over external carriage is that many of the carriage environment concerns are alleviated. However, some carriage environment concerns could be greater for internal carriage than that of external carriage. Examples include high vibration and acoustic loads when the carriage bay doors are open.

Missile Carriage/Launch Compatibility

This assessment of missile carriage and launch compatibility addresses the design considerations of launch platform compatibility constraints, firepower, launcher alternatives, compressed carriage, and standard suspension requirements.

Launch platform compatibility constraints. Carriage constraints for missiles on surface ships, submarines, and aircraft are shown in Figure 6. Cross-platform compatibility is desirable for a missile system. A larger total buy of missiles for cross-platform application has benefits of lower unit production cost and lower logistics cost. Referring to the figure, in the case of the US standard Vertical Launch System (VLS) for surface ships, the physical constraints are 22 in x 22 in x 256 in. Maximum weight is 3400 lb. US submarines have a similar standard launcher that is circular in cross section. The submarine Canister Launch System (CLS) has a diameter constraint of 22 inches and a length constraint of 256 inches. Maximum missile weight for the CLS is the same as VLS, 3400 lb. Finally, aircraft launch platforms include tactical fighters, bombers, and helicopters. Shown in the figure is an example of

a small fighter aircraft, the F-18C. The F-18C carries weapons externally on pylons and rails. Other aircraft may also have an additional capability of internal carriage. For an aircraft using external carriage, the missile span constraint is about 24 in x 24 in. Length constraint is about 168 in, and maximum missile weight varies from about 1,000 to 3,000 lb, depending upon the aircraft. There is a strong desire for light weight precision strike missiles, in order to maximize the firepower of small aircraft, such as the F-18C. Small aircraft can have severe maximum weight constraints.

Aircraft store compatibility wind tunnel tests are conducted to determine store carriage loads and store separation forces, moments, and trajectories. Figure 7 shows wind tunnel installations of aircraft and store models. Note that a typical store loadout has closely spaced stores. The local air flow around a store is difficult to predict. There is a complex flow field interaction of a store with the aircraft and also with the adjacent stores.

Firepower. Figure 8 shows how day/night operation, firepower objectives, and weapons loadout affect the maximum allowable weight of a precision strike missile. Shown are examples of the F-18C and F-18E aircraft. Note that the F-18C aircraft has less capability than the F-18E in all loadout configurations. Figure 8 shows a large difference in maximum allowable missile weight for day versus night operation. The difference is due to the additional fuel that must be reserved for night operation off an aircraft carrier. The maximum weapon weight shown in the curves must also be reduced to account for limits in asymmetric carriage (2,500 lb for inboard carriage and 1,500 lb for outboard carriage). Finally, note the reduction in maximum allowable missile weight as the loadout configuration is changed from a clean aircraft with precision strike missile(s) to other configurations. Five other loadout configurations are the precision strike missile(s) plus 1) a centerline fuel tank, 2) two inboard fuel tanks, 3) centerline fuel tank plus two Sidewinder air-to-air missiles, 4) centerline fuel tank plus two anti-radiation missiles (ARM), and 5) two inboard fuel tanks plus two Sidewinders. The maximum allowable weight of a single precision strike missile on the F-18E is about 4,800 lb under ideal conditions. For an F-18C operating at night with two inboard fuel tanks and two Sidewinders, the maximum allowable weight of a precision strike missile is much lower, about 1,800 lb. In the case of carriage of two precision strike missiles, the F-18E under ideal conditions can carry a missile weighing up to 2,400 lb. At the other extreme for an F-18C loadout of two precision strike missiles, operating at night with the addition of two inboard fuel tanks and two Sidewinders requires that the precision strike missile weigh less than 900 lb. A precision strike missile weight of about 1,400 lb is probably a good compromise for the example of F-18C/E aircraft

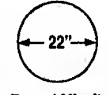

Launch Platform	Launcher	Maximum Body Shape	Maximum Length	Maximum Weight
 Surface Ships	 Surface VLS	 Square Missile	256"	3400 lb
 Submarines	 Sub-CLS	 Round Missile	256"	3400 lb
 Aircraft	 •Ext / Int •Pylon / Rail	24" x 24"	168"	1000 lb to 3000 lb

Figure 6. Missile Shape, Size, and Weight Are Driven by Launch Platform Compatibility.

Figure 7. Store Separation Wind Tunnel Tests Are Required for Missile/Aircraft Compatibility.

Figure 8. Light Missiles Enhance Firepower

integration. It allows two weapons on the F-18C for unrestricted day operation, two weapons on the F-18E for near unrestricted night operation, and three weapons on the F-18E for day operation with two inboard fuel tanks.

Launcher alternatives. Figure 9 shows examples of missile carriage on US standard rail and ejection launchers. In the upper left is an AGM-114 Hellfire II missile on a helicopter rail launcher. Rail launchers are particularly suited to light weight, high thrust missiles such as Hellfire. Hellfire weighs 100 lb, with a launch thrust-to-weight of about 30:1. Hellfire has a laser seeker with +/- 30 degrees field of regard. A launch platform integration consideration is that the missile must be mounted sufficiently far forward on the aircraft such that the seeker line-of-sight to the target is not obscured by the launch platform. Another concern for rail launch is the effect of tip off error. A rail-launched missile has roll, pitch and yaw rate excursions as it moves down the rail, due to missile/rail clearances and the aeroelasticity of the launcher. Tip off error at launch has an effect on the missile miss distance at its minimum effective range. Another contributor to missile miss distance at the minimum effective range is the effect of helicopter downwash on the missile angle of attack at launch. In the upper right corner of Figure 9 is an AGM-88 HARM missile. Most precision strike missiles, including HARM, use ejection launch. HARM has an anti-radiation homing seeker. The installation pylon must also be sufficiently far forward on the aircraft that the seeker line-of-sight to the target is not obscured by the launch platform. The pylon contains ejection cartridges that provide downward velocity and pitch rate to the missile at launch, aiding safe and accurate separation. Suspension of the missile is such that the missile center-of-gravity is midway between the ejectors. A concern during launch is the aircraft local angle of attack and local angle of sideslip effects on the missile flight trajectory. Finally, the bottom of Figure 9 shows an example of internal carriage. Eight AGM-69 SRAM missiles are shown on a bomber rotary launcher. The missiles are ejected from the bay at an ejection velocity of about 20 ft/sec. Concerns for internal bay carriage include bay acoustics, bay vibration, and flow field angularities near the aircraft.

Compressed carriage. Compressed carriage has reduced span missile surfaces during carriage, allowing closer spacing of adjacent missiles on the launch platform. Approaches for compressed carriage include reduced span/longer chord surfaces, folded surfaces, wraparound surfaces, and switch blade surfaces. Figure 10 illustrates the benefits of compressed carriage. A baseline AMRAAM missile in an F-22 internal bay allows two missiles per bay. However, compressed carriage AMRAAM can be packaged three missiles per bay, a 50% increase in firepower loadout.

Store Weight / Parameter	30 Inch Suspension	14 Inch Suspension
<ul style="list-style-type: none"> Weight Up to 100 lb Lug height (in) Min ejector area (in x in) 	Not Applicable	Yes 0.75 4.0 x 26.0
<ul style="list-style-type: none"> Weight 101 to 1,450 lb Lug height (in) Min lug well (in) Min ejector area (in x in) 	Yes 1.35 0.515 4.0 x 36.0	Yes 1.00 0.515 4.0 x 26.0
<ul style="list-style-type: none"> Weight Over 1,451 lb Lug height (in) Min lug well (in) Min ejector area (in x in) 	Yes 1.35 1.080 4.0 x 36.0	Not Applicable

Table 2. MIL-STD-8591 Ejection Launcher Requirements.

Standard suspension requirements. Store suspension requirements for ejection launchers, based on US MIL-STD-8591 are summarized in Table 2. Shown are store weight and parameters for light weight stores (up to 100 lb), medium weight stores (101 to 1,450 lb), and heavy weight stores (over 1,451 lb). Suspension alternatives are 30 inch and 14 inch suspension systems. For an ejected store weight up to 100 lb, only the 14 inch suspension can be used. For a light weight missile on the 14 inch suspension, the lug height and minimum ejector pad area are prescribed as 0.75 inch and 4.0 in x 26.0 in respectively. For a medium weight missile, with a weight between 101 and 1,450 lb, either the 14 inch suspension or a 30 inch suspension may be used. Medium weight ejected stores have larger required lug height and minimum ejector area. They also require lug wells. The required lug wells could have a strong impact on the missile internal structure design. For example, in some cases the rocket motor overlaps the missile center of gravity, and it may be difficult to accommodate lug wells in the rocket motor case. A strong back may be required, similar to that of the AGM-69 SRAM missile. For a heavy missile with a weight over 1,451 lb, only the 30 inch suspension can be used. MIL-STD-8591 requires that the lugs have a deeper well if the missile weighs more than 1,451 lb.

Survivability (Missile Observables and Insensitive Munitions) Compatibility

This assessment of survivability (missile observables and insensitive munitions) compatibility addresses the design considerations of internal carriage, reduced observable plumes, and insensitive munitions.

Internal carriage. Alternative approaches for missile carriage include conventional external carriage, conformal carriage, and internal carriage. Conventional external carriage has disadvantages of high radar cross section (RCS), high carriage drag, and potentially adverse aeroelastic, stability, and control interactions with the aircraft platform. Conformal carriage has an advantage of reduced RCS and drag compared to conventional carriage. However, the

Figure 9. Precision Strike Missile/Aircraft Launch Integration Considerations.

Figure 10. Compressed Carriage Missiles Provide Higher Firepower for Aircraft with Internal Weapon Bays.

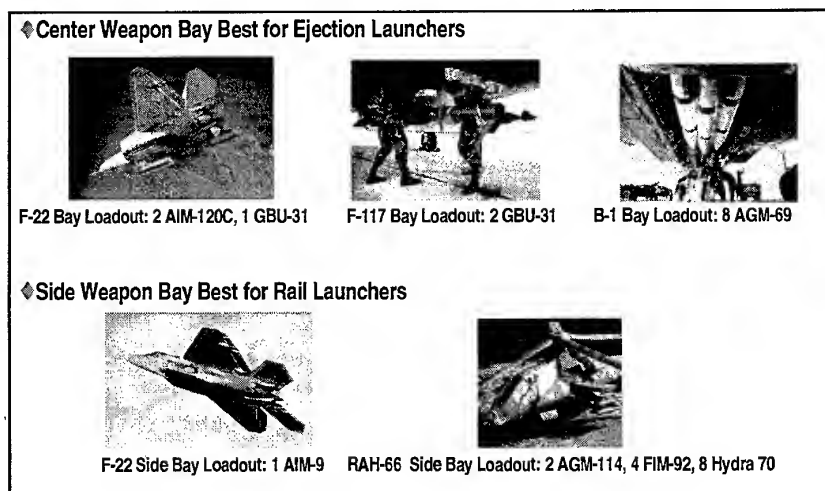

Figure 11. Internal Bay Carriage Has Low Observables.

preferred approach for the lowest carriage RCS and the lowest drag is internal carriage. Figure 11 shows examples of internal carriage and loadouts for a low observable fighter, bomber, and helicopter. In the upper left is shown the F-22 internal center bay. A typical loadout of the F-22 center bay is two AMRAAMs plus one 2,000 lb JDAM. Ejection launchers are provided for AMRAAM and JDAM. The F-117 has a similar weapons bay. A typical loadout for the F-117 is two JDAMs. The B-1 bomber has three bays. Each bay has a rotary launcher for ejection of missiles and bombs. A standard loadout is eight AGM-69s per bay. In the lower left of the figure is a photograph of an F-22 side bay. The F-22 has two side carriage bays. Each bay is capable of carrying a single Sidewinder missile on a rail launcher. The RAH-66 Comanche helicopter has two side bays with rail launchers. Each bay has a typical loadout of one Hellfire missile plus two Stinger missiles and four Hydra 70 rockets.

Reduced observable plumes. Table 3 shows tradeoffs of rocket motor performance versus safety and observable concerns. The highest performance propellants unfortunately also have high observable smoke particles (e.g., Al_2O_3), due to metal fuels such as aluminum. An initial approach to reduce plume observables is reduced smoke motors. Reduced smoke motors replace the metal fuel with a binder fuel such as HTPB. The performance and insensitive munition capability of reduced smoke motors is slightly lower than that of high smoke motors. Reduced smoke propellants can still have visual observables from a hydrogen chloride contrail. The HCl contrail occurs at low atmospheric temperature. A third type of propellant is minimum smoke propellant. Minimum smoke propellants eliminate the HCl contrail by eliminating ammonium perchlorate as an oxidizer, resulting in lower visual observables. The performance and safety of current minimum smoke propellants is not as good as that of high smoke propellants. Examples of current minimum smoke propellants are cross-linked double base (XLDB) propellants such as HMX and RDX. An example of a new minimum smoke propellant is the US Navy China Lake CL-20 propellant. CL-20 is chemically related to current XLDB nitramine explosives. However, CL-20 is a cyclic polynitramine, with a unique caged structure that provides higher crystal density, heat of formation, and oxidizer-to-fuel ratio. CL-20 propellant has 10-20% higher performance than HMX and RDX. CL-20 also has reduced shock sensitivity (class 1.3 versus 1.1) and milder cookoff reaction than either HMX or RDX.

Figure 12 illustrates the plume observables of high smoke, reduced smoke, and minimum smoke propellants. The relatively old Sparrow missile rocket motor is a representative high smoke motor. The high smoke plume is shown in the upper left corner of the figure. Sparrow has high smoke Al_2O_3 particles from

aluminum fuel. Also shown is an example of a reduced smoke rocket motor. AMRAAM is a more recent missile, with a reduced smoke motor. It still has a contrail of HCl from the ammonium perchlorate oxidizer. The HCl contrail occurs if the atmospheric temperature is less than -10° Fahrenheit, corresponding to altitudes greater than about 20,000 feet. Finally, the far upper right photograph is an example of a minimum smoke rocket motor. Javelin is a recent missile with a minimum smoke motor. It has almost no smoke from either the launch motor or the flight motor, enhancing the survivability of the gunner. Minimum smoke propellants can have an H_2O (ice) contrail if the atmospheric temperature is less than -5° Fahrenheit, corresponding to altitudes greater than about 27,000 feet.

Insensitive Munitions. Insensitive munitions have high payoff in improving launch platform survivability. The critical subsystems are the rocket motor propellant/engine fuel and the warhead. In the US the design considerations for insensitive munitions are based on MIL-STD-2105B. MIL-STD-2105B includes design considerations of hardening against threat weapons, safety from fire, dropping the weapon, extremes in environmental temperature, missile vibration, and operation off an aircraft carrier. Hardening against threat weapons includes considerations of fragment impact and blast. Cookoff from a fire includes the type of fire (slow cookoff, fast cookoff) and the reaction to the fire (e.g., burning, detonation). Drop considerations include ground maintenance personnel dropping the missile during handling. The environmental temperature includes both very low temperatures that could damage the rocket motor and very high temperatures that could cause detonation of the warhead or rocket motor. Missile vibration includes the dynamic acceleration imparted by carriage on the launch platform. Finally, aircraft carrier operation includes the shock of aircraft landing sink rates as high as 18 ft/sec.

Type	I_{sp} , Specific Impulse, sec	ρ , Density, lb / in ³	Burn Rate @ 1,000 psi, in / sec	Hazard	Observables

Simulation/Design Validation Technology

Erik Berglund
Defence Research Establishment
172 90 Stockholm, Sweden
eberglund@foa.se

Summary

Simulation plays an increasingly important role in the development of new missile systems. This paper contains a brief overview of the various types of simulation models used in different phases of design and evaluation. The main emphasis is placed on trajectory simulation models. The usefulness of different trajectory models for different purposes is treated. A recommendation is to avoid using more complicated models than are required to address the problem of interest. The problem of using a very limited number of test firings to validate a highly complex model is mentioned.

Introduction

In the design of a new missile system, as well as in the development of tactics, modelling and simulation plays an increasingly important role. The main reason for this is, of course, to save money. The number of test firings, which are expensive, has declined and more of the system validation is now done using simulations. An example of this is given in table 1.

Modelling and simulation is a concept that includes many different aspects. Modelling and simulation of missiles can be used for many different purposes, e.g.:

- Concept studies and preliminary design
- System design
- Verification of system performance
- Assessment and analysis of systems
- Assessment and development of tactics
- Training of operators
- Threat assessment

Usually the models used in early design studies done by industry or in early studies by the government to define requirements are much simpler than the models used for final design and requirement verification.

In the development of a missile system it is common to develop a hierarchy of models from small subsystems to the entire system. All models are based on equations describing the relevant physical phenomena and on data describing the studied missile system.

Issues of vital importance to all models are verification and validation. Verification is the process to assure that the simulation programme is a true representation of the underlying physical model, while validation is the process to assure that the model is a good representation of reality, given the questions to be treated by the model.

The most relevant models for assessment of missile system performance and the transfer of data between the models are outlined in figure 1. The following text will mainly concentrate on trajectory simulation, missile system design, and verification of system performance.

Year	Missile	Development	Evaluation	Total test firings	Simulation model
1951-58	Firestreak	209	94	303	None
1957-66	Red Top	77	40	117	Analog
1964-72	Martel	24	27	51	Hybrid
1973-78	Sky Flash	12	10	22	Digital

Table 1. Number of test firings during development and evaluation. (Data from British Aerospace)

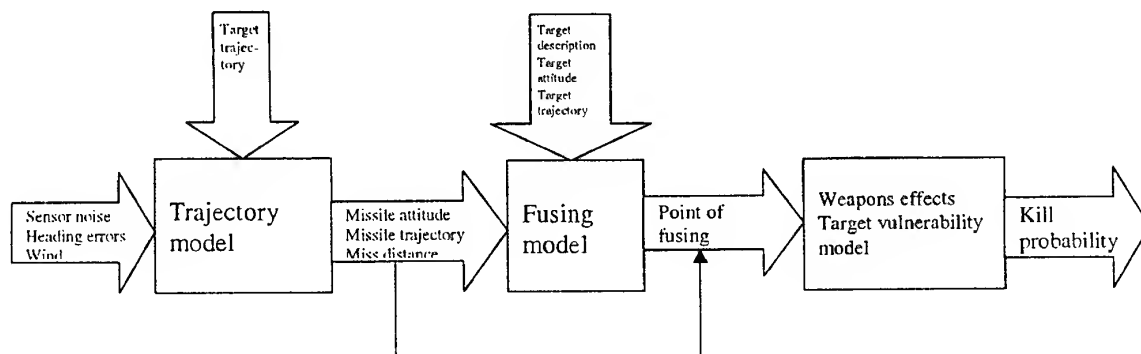

Figure 1. Models for missile system assessment.

Trajectory Models

Trajectory simulation models can differ widely in complexity. They can be categorised according to several principles:

- 2D or 3D
- Linear or non-linear
- Kinematic or dynamic
- All digital or hardware-in-the-loop
- One-on-one or many-on-many

Practically all possible combinations given by the above alternatives can be used.

Bellow follows a discussion first on various types of one-on-one models and then on many-on-many models, mainly focused on the difficulties with choosing the correct measures of effectiveness (MoE). Textbooks on trajectory models include Zarchan.

2D or 3D Model

As a 2D model is significantly easier both to develop and to use, it must be recommended to start the modelling and simulation work with a 2D model. Further reasons for using 2D models are that in many cases most of the motion takes place in a plane and also that many roll stable missiles have weak cross coupling between the channels.

Linear or Non-Linear

A missile model is highly non-linear in many of its parts. Yet linear models are often used for analysis and design. Advantages from using linear models include:

- Smaller model
- Super positioning applies, i.e. disturbances can be treated separately and their effects can be added.
- Standard design tools can be used for controller design.
- The method of adjoints can be used to calculate the effects of stochastic disturbances in an analytical way, thus avoiding the use of multiple Monte Carlo simulations.

Although linear models play an important part of controller design, more complex non-linear models have to be used to assess the performance of the missile and the control system.

Modern software, such as Matlab/Simulink, allows rapid linearisation of complex non-linear systems and provides an environment for design and simulation.

Kinematic Models

A kinematic model is a model where motion takes place, but where the cause of the motion is not treated, i.e. the dynamics is not included. In a missile model this means that the missile follows an ideal trajectory according to the guidance law unless some imposed limits, such as maximal range, are reached.

Kinematic models can be used to obtain launch and intercept zones. Kinematic models do, however, not provide any miss distance.

Required data for a kinematic model include:

- Basic aerodynamics
- Thrust
- Guidance law
- Limitations such as
 - Maximal time of flight
 - Minimal velocity
 - Maximal angle of attack
 - Maximal load factor
 - Minimal closing velocity (for fusing)
 - Field of view of command receiver or seeker
 - Maximal tracking angular velocity

A launch zone, which is a typical result given by several runs of a kinematic model is shown in figure 2. Kinematic models can also be used to calculate no-escape zones. A no-escape zone is the subset of the launch zone, where a launched missile is guaranteed to hit even if the target evades with maximal acceleration. An example of a no-escape zone is given in figure 3.

The limited amount of data required by kinematic models make them well suited for preliminary analysis in the early stages of design and also for analysis of foreign, potentially hostile, systems.

Dynamic Models

A dynamic model calculates the trajectory of the missile using Newton's equations of motion for a rigid body.

A dynamic model requires detailed data such as:

- Aerodynamics
- Thrust
- Guidance and control system
- Disturbances, e.g. measurement noise

The output from a dynamic model consists of time records of all variables, including the missile trajectory and also the point of impact or the miss distance.

Dynamic models always contain transformations between coordinate systems. The missile dynamics is normally calculated in a missile body-fixed coordinate system. The missile velocities obtained in the body-fixed system are then transformed to an earth-fixed system where they are integrated to positions.

Figure 2. Launch zone for a typical line-of-sight guided surface-to-air missile. The limiting factors are noted.

Figure 3. Example of no-escape zone (inner zone) and launch zone against a straight and level target for a surface-to-air missile using proportional navigation.

Hardware-in-the-loop

Even though computer models have progressed very rapidly over the last decades, there is still a need for hardware-in-the-loop (HWIL) simulation. In HWIL simulations the normal approach is to use real hardware for the seeker in the missile and to use software to simulate the fly out of the missile. The seeker is mounted on a turn table in a room where the background signature can be carefully controlled (an anechoic chamber in the case of radar seekers). A target scenario is displayed for the seeker and the seeker output is fed into a digital model where the dynamics of the missile are simulated. The motion of the missile is then fed to the turn table, such that the seeker is moved in accordance to the simulated missile motion.

Many-on-many

For assessments at a higher systems level many-on-many models are often used. A many-on-many model treats scenarios with more than one weapon on each side.

Assessment on higher levels is far more complicated than assessment on a one-on-one basis. The main reasons for this are that the system to be assessed contains not only technology but also humans and decision making, and also that it is much less clear what constitutes success.

An example of the difficulties of defining success can be taken from the Gulf War. The US Patriot surface-to-air missile was used to defend against attacking Scud missiles. The post war analysis has shown that the Patriots had very little, if any, effect on the incoming warheads. To conclude from this that the Patriot had no effect in the war is to make a severe error. Through television, millions of people all over the World could follow the Patriot missiles as they rose to the skies to ward off the incoming danger. By deploying Patriots to Saudi Arabia and Israel the US clearly showed concern for her allies' security. The conclusion is therefore that the Patriot had great effect, despite perhaps not scoring a single kill.

A further example of difficulties associated to many-on-many assessment can be taken from

Berglund and Hansson. An assessment was made of a proposal to purchase a new and much improved surveillance radar to the Swedish Hawk surface-to-air missile system. The old system, called RBS77, had an old 2D radar with somewhat limited performance, while the proposed new system (RBS87) had a modern 3D radar with much better performance, not least in an environment with electronic warfare. The two systems were assessed in a many-on-many model, where several scenarios were used. The aggressor employed different weapons (iron bombs, guided missiles, stand-off weapons) and tactics (low or high altitude, defence suppression or not etc). All the scenarios were run with or without enemy use of electronic warfare. When the number of killed enemy aircraft was summed up, the result was according to table 2.

	Kill ratio without enemy EW	Kill ratio with enemy EW
Old RBS77	59%	53%
New RBS87	58%	42%

Table 2. Kill ratios in scenarios with and without electronic warfare.

The surprising results motivated a closer look on the simulation results, which showed that the main reason for the results was that the main effect of the electronic jamming was to reduce the range of the surveillance radar. The reduced detection range resulted in missile launch at shorter range and consequently shorter times of flight. However the kill ratio per launched missile increased as the shorter time of flight resulted in less time for enemy counter measures such as manoeuvres. As most of the scenarios provided a target rich environment, the final result of the low performance radar and the enemy jamming was a high kill ratio. A conclusion is that kill ratio not was a good measure of effectiveness for assessment of the value of the modern radar.

A conclusion from the above example is also that great emphasis should be placed on the formulation of scenarios to reflect the questions to be treated and that the use of overly large and complicated models should be avoided. Qualified analysts are also needed throughout the process.

The choice of measure of effectiveness is further complicated by the changing nature of armed conflicts. While it was fairly straight forward to assess effectiveness in the major war that was envisioned during the Cold War, it is much more complicated in the broader range of conflicts envisioned today. Present and future conflicts are likely to take place in a peace time environment, where much of the focus is on public opinion and

media relations. A weapon of today must not only disable the enemy, it must avoid collateral damage and it must also look good on television.

So far there has not been established any new set of relevant measures of effectiveness to reflect asymmetrical conflicts in a peace time environment.

Performance verification

As was previously mentioned simulation models play a major part in the process of performance verification.

Presently there does not exist any established theory for how to verify the performance of a highly complex system given only a few real test firings and simulations. Some of the problems facing those working with verification and some of the present practice are outlined below.

In the development of a missile system the real physical system is usually developed in parallel with simulation models. This process is described in figure 4, perhaps following a more logical bottom up approach than is usually the case.

A detailed 6 degree of freedom trajectory simulation model is developed. The detailed model either contains detailed models of subsystems, such as the seeker, or simpler descriptions based on detailed submodels. The models of the subsystems are in each case validated against experiments and tests. A hierarchy of models is thus developed and the general hope is that models based on validated submodels have a good chance of being good representations of reality.

The number of real system tests, i.e. live test firings, is normally very small, perhaps less than 10. Data from the test firings are recorded and used both as a basis for model validation and as a basis for system performance verification. Simulations of the exact test firings are conducted and a comparison with the test firings is made. The purpose of the comparison is to validate the model, but often some changes have to be added to the model. The model is then to be declared as valid, often by a government agency.

The next step is to use the model to simulate a large number of scenarios and to use the simulation results to verify system performance.

In this process of model validation and system performance verification there are many unsolved problems:

- How should a comparison between live firings and performance requirements be conducted given statistical properties and measurement quality?
- How should the live firings be compared to post-test simulations given statistical properties and measurement quality?

- Is it possible to use the test firings both to update the model and to validate it?
- How should the scenario for the test firings be chosen?
- How many test firings are required given the complexity of the system?
- How should the results from test firings and simulation be compared to the performance requirements in order to verify the system performance?

As these questions currently remain unanswered it must be concluded that validation and verification despite great efforts still relies, at least to some extent, on faith. However, as experience shows that reasonable results are achieved through this process, there seems to be reasons to have faith.

Abstract

The goal of this paper is to project those video or picture based Automatic Target Recognition (ATR) systems likely to enter military inventories and alter mission planning in the year 2000 and beyond. Therefore, this paper avoids a discussion of specific technical approaches and their relative merits that often leads into proprietary or classified discussions. An emphasis is placed on the attributes of ATR as a military product and the factors that will determine the success or failure of efforts to move them in large quantities into military inventories. Some suggestions will be given on how the time to market can be shortened and where video ATR systems will first appear on the post cold war battlefield.

Introduction

ATR in some form has been part of military systems for many years and some of these systems operate total autonomously. It is in the area of Video ATR (VATR) systems where the human operator has played an unchallenged role because of the large quantities of data that must be processed rapidly. Surpassing the ability of the human mind to recognize military objects on the battlefield is a difficult challenge. With the advent of small, affordable video computers spawned by a growing commercial market, the potential exists to replace human operators in, at least, a portion of those functions requiring video data processing and target recognition.

The author believes that an objective look at the recent history of efforts to develop ATR as a product and sell that product to the guided missile user community has proven largely unsuccessful. Some people point to a need for even faster computers that will appear each year and the need to incorporate modern computer interfaces between the weapons and the platforms that launch them. New aircraft such as the F-22 and Joint Strike Fighter (JSF) will certainly contain modern computer interfaces. All of these shortfalls impact the size of the ATR market but do not necessarily account for the growing view that systems recently tested don't validate the claims of their developers when tested in settings representative of modern battlefields. The author believes that too much effort has been spent on new approaches to ATR and this means new algorithms, software, plus testing of these algorithms. Too little time has been spent on the system

engineering that helps define a product and its relationship to other products in a context that potential customers can make an informed buy decision. This paper treats the ATR as a system or product and explores the functions they perform, the needs they fill, and the ways they are intended to be used by the military community.

ATR High Level Architecture

ATR can be thought of as a computer and software that tries to estimate what is the structure of the battlefield in front of the sensor base on three measurements; a.) knowledge of the transmitted or natural battlefield illumination, b.) observations of the reflected or emitted energy from the battlefield and c.) reconnaissance data about the battlefield. Figure 1 illustrates how the ATR uses all the data available to try and estimate the current state or makeup of the battlefield similar to the human observer. Because the ATR cannot process this information instantaneously, the data it provides the warfighter is late. This delay is more mission critical to a missile than an intelligence unit.

Levels of ATR

Figure 2 illustrates the various levels of ATR depending on the type of sensor and to what degree the target is resolved into more than a single point. If the target is a single point, the ATR designer must struggle to find a discriminator other than size or textual content. If the target is the brightest object on the battlefield, a simple threshold test suffices which is normally called detection. Beyond brightness, the design must look for motion with time, brightness fluctuations or patterns of points in military type formations such as a convoy on a road. Point target recognition is in many ways the most difficult ATR problem but these types of ATR systems have been used for years on such weapons as radar guided, antiship missiles.

If the target is bigger than a point but cannot be resolved into recognizable patterns, the designer can still exploit the spatial extent of the blob and blob detection algorithms have been used for many years. Features such as height to width ratio or area can be effective discriminants. Classifying the type of target is however not possible by these measurements alone.

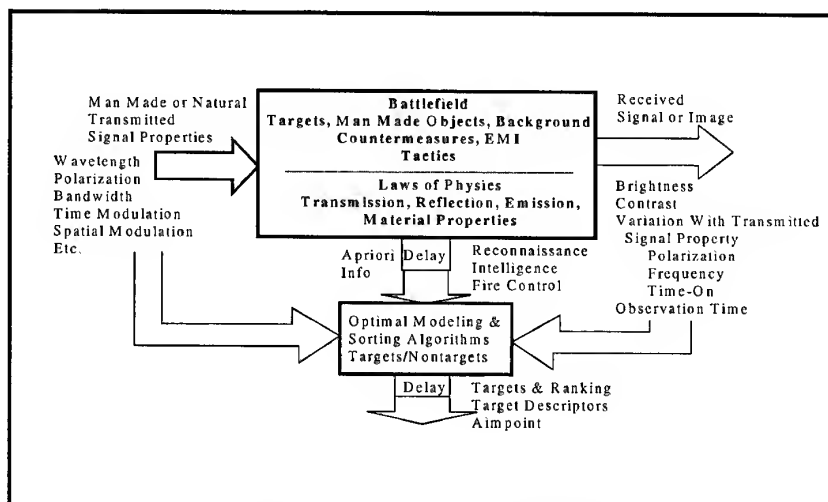

Figure 1 ATR High Level Architecture

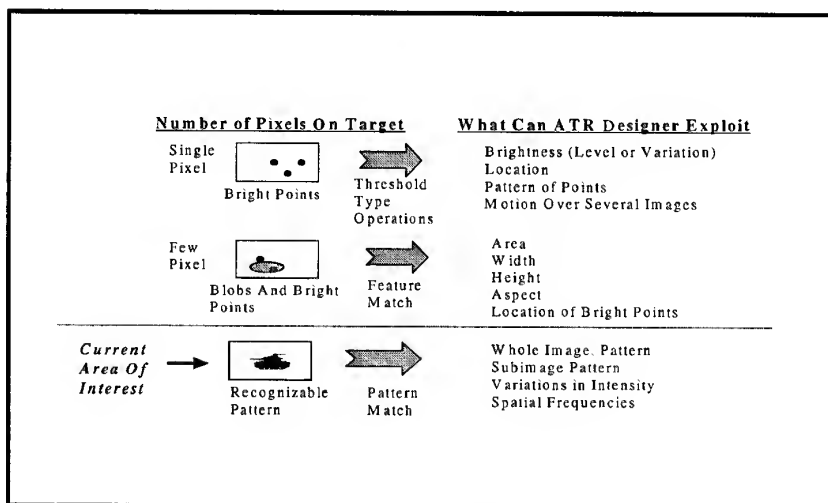

Figure 2 Levels of ATR

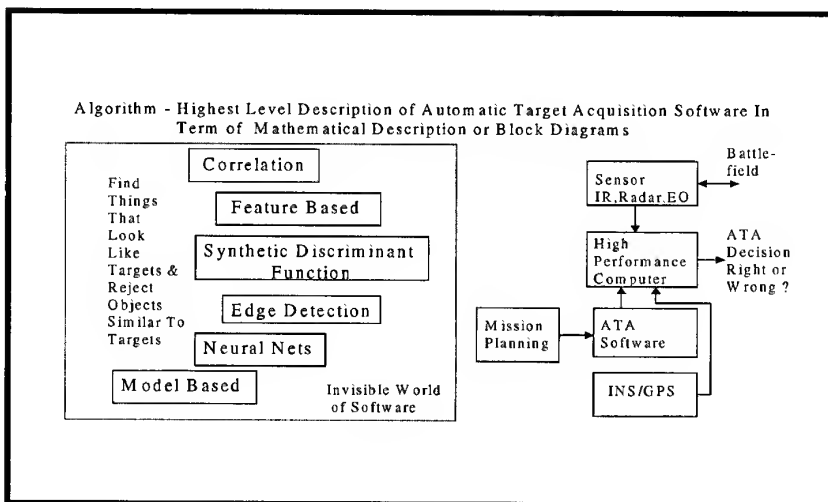

Figure 3 ATR Algorithms

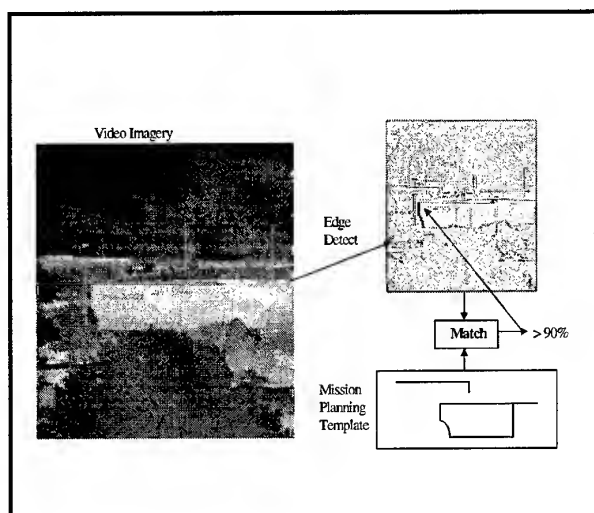

Figure 4 Standoff Weapon ATR

Recently with the advent of high resolution snapshot sensors like Synthetic Aperture Radar (SAR) or Imaging Infrared systems using detector arrays of thousands of detectors, sensors produce target pictures which the human observer can exploit very efficiently for precision man-in-loop guidance. With the explosion of the information content has come the difficulty of processing all this information and matching the tremendous ability of the human mind. As computers progress from being efficient manipulators of textual data, speech data, and very soon, picture data, the dawn of video based ATR appears to be only a matter of time. Although, it might even appear first in a commercial form rather than a restricted military form once a profitable commercial market develops.

ATR As An Algorithm

ATR presentations are often centered around algorithm discussions. The algorithm is held to be highly proprietary and better than all other algorithms. The algorithm being the mathematics or recipe of the software design. As Figure 3 illustrates, there are a large and diverse number of algorithmic approaches to ATR. When mixes of these algorithms are considered, the number of choices becomes even larger. Each algorithm has its own group of advocates who may cluster around some academic discipline such as neural science, computer science, a branch of mathematics or some branch of engineering. Some even spawned new computer languages and processor designs. Prior to the dawn of algorithms as the core of ATR, high speed military processors were often found at the core but the decline in the market for military electronics compared to commercial electronics brought a rapid decline to the number of these processors. Often these special military processors were obsolete before they could find a home in a military product and corporations were

unwilling to continuously invest in upgrades to both hardware and software tools with low expectation of achieving a significant return on investment.

Fixed Target ATR

Figure 4 illustrates perhaps one of the less stressful ATR problems associated with strike warfare. Even this problem of finding a large building or bridge has only recently been considered solved, at least, by a portion of the ATR community. A large building is made up of edges and a template made up of a sufficient number of these edges can be sufficient to find an aimpoint by matching the edge template to the incoming sensor edge detected image. The problem is complicated by lack of knowledge about the missile approach angles to the target but fortunately GPS fills this information gap for fixed targets. In this mission area, GPS has come to the aid of ATR by reducing the workload for man-in-the-loop systems. Once the attention of ATR moves from large fixed target to moving or relocatable target ATR, the challenge remains high.

Diversity of ATR

One of the aspects of ATR that complicates the transition from a technology to a product is the diversity of the ATR community as illustrated in Figure 5. Although, diversity is good in achieving technological breakthroughs, it is not necessarily good when it comes time to producing a marketable product that can be sold for a profit. The algorithm designer always feels his algorithms need more tuning or new algorithms need to be added increasing the computational complexity. The target modeler can always build better models and the sensor designer can always improve the sensor performance. In this diverse community there is often a key person missing who is necessary to define a product and that is the ATR systems engineer. The ATR systems engineer understands requirements, specifications, acceptance testing, and "Cost as an Independent Variable." The ATR technologist see these concepts as separate from the ATR development and tasks that follow rather than lead the ATR design which is not a product oriented view but technology oriented view. A need exists to grow ATR systems engineers to support the transition from technology to product. As Figure 6 illustrates, there has been growth in this area over the years as the need for increased funding levels and sustaining existing funding levels have altered the technologists view of ATR closer to a product.

Transition To A Product

This paper has suggested that ATR is a technology on the verge of becoming a product. There is a threshold, however, that still needs to be crossed and unfilled expectations by customers may delay the time when the military crosses this threshold. Figure 7 illustrates

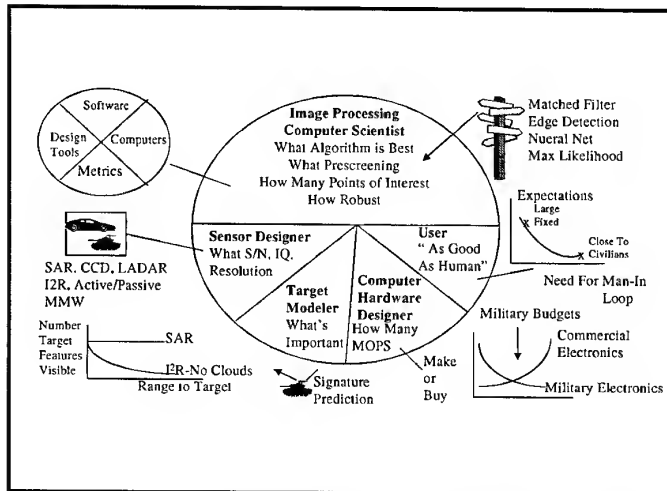

Figure 5 Diversity In ATR Community

the main pillars of the bridge required for ATR to cross this threshold and they centers around the concept of being in the right place at the right time. A major military program will surface which needs ATR but might move forward without ATR if it isn't production ready. Similar to past missile programs needing adverse weather performance but being unable to find radar seeker products providing that capability at an affordable price have moved forward accepting only day-night performance. Mature ATR designs must be available and this implies software running in real time on an affordable processor that fits into the allocated volume. The willingness of customers to proceed will depend a great deal on how mission critical the need is for ATR and the strength of the acceptance testing which supports a production go ahead decision.

Since ATR designs revolve around software and a computer, there is good reason to expect ATR to find

its first markets in the civilian area. Once these commercial products receive public recognition and approval, the military may find itself in a follower position or developing militarized versions of commercial products. The author believe this scenario is the most likely one since the commercial uses of ATR seem limitless and video computers are already becoming an affordable commercial product as the movie industry has proven with ever increasing levels of animation.

The Military Development Cycle

What in the past has been the military ATR development cycle is illustrated in Figure 8. This cycle is not unlike other technologies waiting the time when they will transition into useful products. The cycle starts with a company hiring or promoting from within an algorithm expert who develops a non-real time simulation of his selection of an optimal

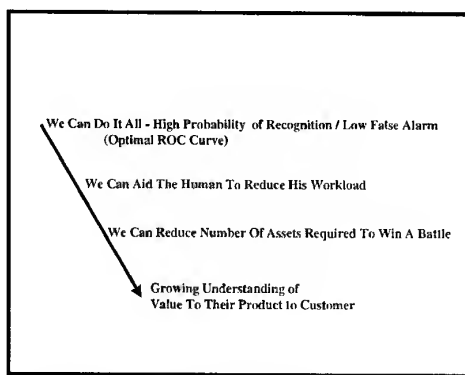

Figure 6 ATR Changing Vision of Benefits

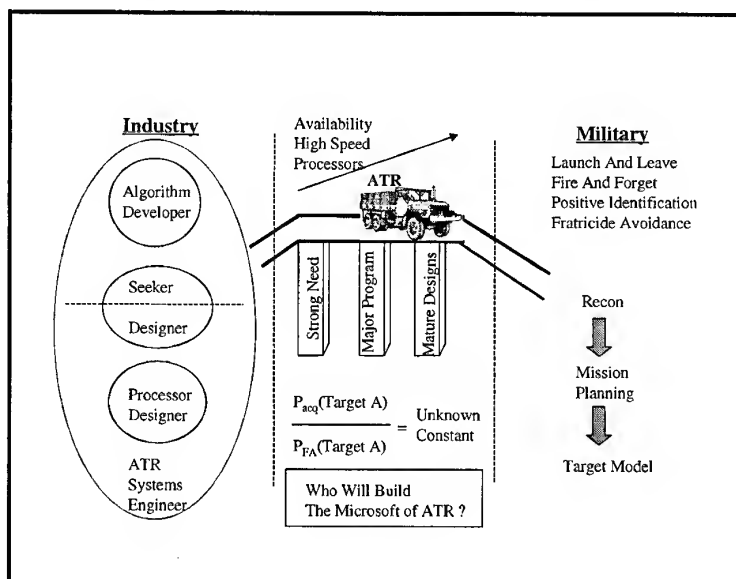

Figure 7 Transitioning To a Product

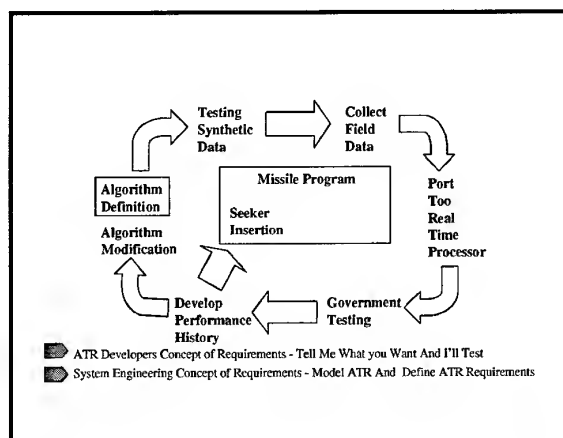

Figure 8 ATR Development Cycle

approach to ATR. This software is often tested with synthetic imagery that allows tight control of the collection geometry and scenario. Once good performance has been achieved, a need develops to validate the software with imagery from a representative sensor for a particular mission area. A captive flight test of the sensor yields a test data set under somewhat controlled test conditions. If this step gives favorable results the software is moved into a real time processor but one that maybe larger than the application could accommodate. At this point, the government may test the ATR system and reach some conclusion as to its utility. The most likely outcome is a need to modify the algorithm and start the process over again. The number of cycles the process goes through depends on what new missile programs are on the horizon that might need this ATR product and the patience of funding sources.

ATR As A System

The systems approach taken in the past to defining ATR as a system is centered on the "black box approach." ATR was sold as a stand alone system only loosely tied to the sensor whose imagery it uses as an input to make a recognition decision. The impact of this black box approach and the arbitrary separation of the ATR function from the sensor function limits ATR system engineering to a computer and software trades space. When it becomes clear at a higher system level that trades need to be made between the complexity of the ATR and the complexity of the sensor, it becomes a very painful process and often leads to an expensive sensor design. There are many reasons why a black box approach to designing an ATR product should be looked at with great skepticism. Almost always, the requirements, flowdown process results in sensor image quality requirements that insist on perfection in all circumstances.

When an ATR product advertises its value to a potential buyer, it normally concentrates on probability of acquisition and false alarm rate or false

alarm density. An ATR system is a user of information so its probability of acquisition is only meaningful if the sensor can provide a good image and that condition doesn't occur with probability one. At times, the scenes or viewing conditions are such that no sensor will provide a good image.

Probability of acquisition is a function of several equally important factors and the equality claimed in Equation (1) is not at all obvious or has it been proven to be true.

$Prob_{acq}$ [Target in ATR Design Space, Sensor Image Quality at ATR Levels, Mission Planning Data Still Current, User Operates ATR Correctly] =

$$Prob[\text{Target in ATR Design Space}] * Prob[\text{Sensor Image Quality at ATR Levels}] * Prob[\text{Mission Planning Data Still Current}] * Prob[\text{User Operates ATR Correctly}]$$

All the factors that the final probability of acquisition depends on are very interrelated. The mission planner needs to know how the sensor and the ATR function. The problem does not nicely partition itself into four, five or more totally separate design problems and all of these factors must be included in the ATR design space.

ATR Requirements

A complete set of ATR requirements must address more than probability of acquisition and false alarm rate. It must address system interfaces and input-output data including such factors as:

1. Inputs into the ATR system
2. Reconnaissance data required to plan a mission
3. Number and types of targets that must be recognized
4. Quality of data products needed
5. Sensor Performance
6. Output to the missile guidance computer
7. Maximum number targets in scene that can be processed
8. Estimate of target types - tank, truck, jeep, etc. that are in the design space
9. Accuracy of target measurements - length, width, area, angle
10. Computer required to host software - throughput and memory
11. Programming language
12. Type of acceptance testing to sell off a product

A complete set of ATR requirements must be addressed by the design similar to a hardware specification for a sensor system.

Number of Pixels on the Target

One basic requirement for an ATR system is number of pixels on the target for the ATR system to achieve a specified level of performance. This number has been

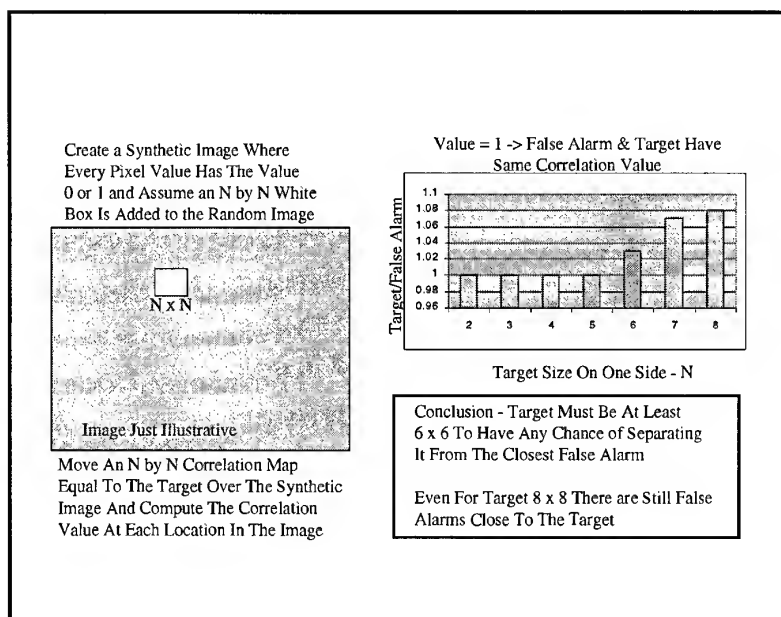

Figure 9 Number of Pixels on Target

hard to extract from the ATR community. However, it is possible to perform a requirements level of analysis that indicates what is needed. Consider Figure 9 which shows one simple approach to answering this question. If the target of interest is a simple square which is N by N pixels of value 1 and it is embedded in a noisy image where the noise has value 0 or 1. This could correspond to an infrared sensor with signal to noise ratio of 1 or an image after edge detection. What is important is the number of times the noise looks like a square, target. The plot on the right of Figure 9 was computed by passing a $N \times N$ template over the 256×256 image then computing the correlation. The plot shows the ratio between the target correlation and the largest noise correlation (false target). A ratio of 1 means you cannot tell the difference between a target and a false target. The plot shows that the target must be 6×6 before there is any separation between target and false targets and even at

8×8 the separation between targets and false targets is low. The 8×8 number has been used at times as the capability of a human observer so this simple analysis correlates with this traditional threshold. More analysis such as this can add further insight into where to reasonably set the bar for ATR performance. In the past this has been a problem for users not knowing what is a reasonable design specification.

Complexity of Template

Another important area where requirements need to be developed is in the area of template complexity. How much detail should be put into a target template. Consider Figure 10 that shows the edge detected image of the same building used previously. Underneath the edge detected image is a simple template created by extracting lines from the buildings

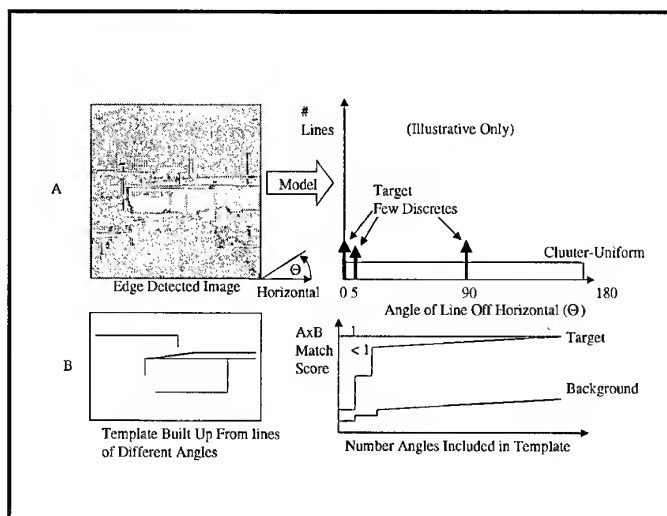

Figure 10 Template Complexity

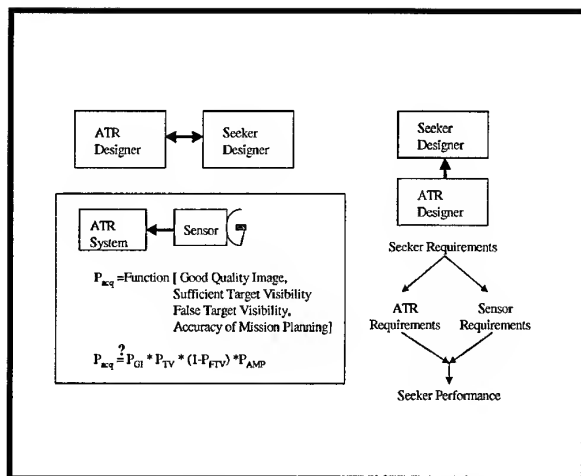

Figure 11 Sensor and ATR Separability

in the image. One question that might be asked is the number of lines that should be used in the template. What the plot on the right illustrates is that the building only has a few line types (distribution of line angles relative to image horizontal) but the clutter has a continuous distribution of line types. The template match score goes up rapidly as you pick the first couple of line types, but after that, there is little increase in match score and adding more lines increases false target recognition more than true target recognition. This example problem illustrates why it is unlikely that any system can achieve zero false alarm rate since every target has something in common with the background and the military tries to increase this similarity using camouflage. The target in Figure 10 is so large, it is not easily missed but ATR must work at longer ranges and distinguish one building from another.

Sensor and ATR Separability

A basic question that needs to be addressed is whether the ATR system and the sensor can be developed separately. As Figure 11 illustrates, this question revolves around whether the key performance parameters can be separated between sensor and ATR and whether the associated requirements can also be separated. It is the authors opinion that they cannot be separated in a real system or product and the two must be developed as an integrated seeker system. The interconnection between the two is too interdependent and design trades cannot be made for one without impacting the other design.

ATR Detection Requirement

Many missile designers have become used to seeing a requirement for target detection. But ATR designers don't generally think in terms of detection as illustrated in Figure 12.

Recognition for an ATR designer is what detection is for a radar moving target indication designer. In a way detection is embedded in recognition and does not separate out into detection followed by recognition. The ATR designer starts his process by finding all those things in an image that could potentially be a target and these are points of interest rather than detections. Points of interest are sorted into valid targets, false alarms or are discarded as non-targets. The ATR system engineer views recognition as a higher level of detection bringing with it more information than target location.

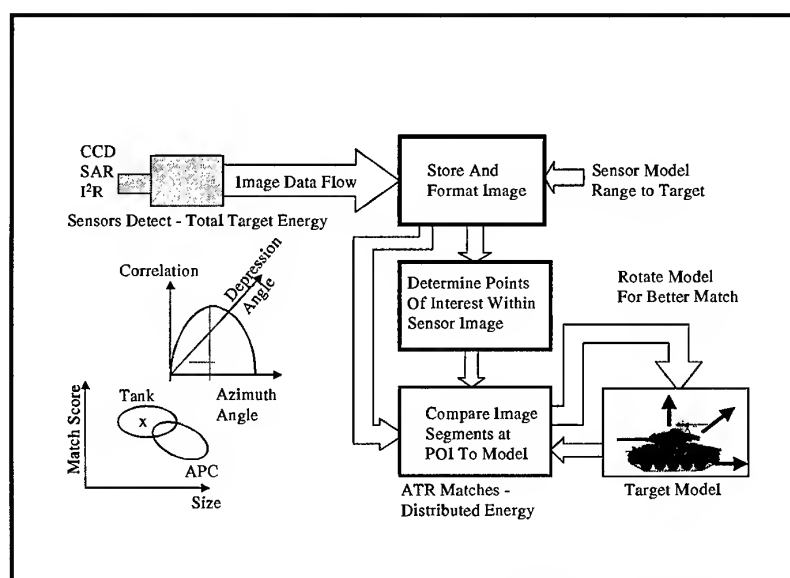

Figure 12 Detection in an ATR System

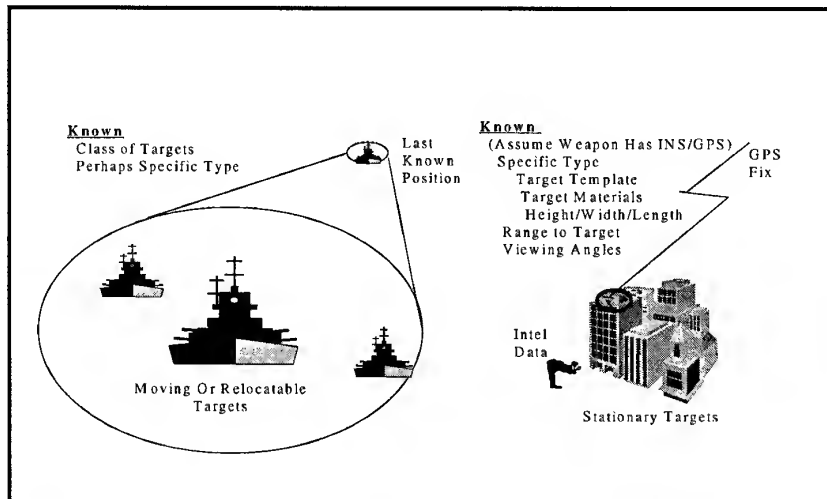

Figure 13 Mission Planning Variability

Variability in Mission Planning

Mission planning is a very important aspect of ATR and an area the ATR designer has very little control over how it is conducted. One past approach has been to try and design for the minimum requirements in the area of mission planning such as one picture of the target. As Figure 13 illustrates there is a great difference between stationary targets and moving targets. Stationary targets can be mapped, surveyed and characterized a long time advance of an actual mission. In this case the designer can perform a high degree of mission planning. Moving targets such as ships at sea are difficult to mission plan and the ATR system must be more robust. Moving targets are also more likely to be targets of opportunity where the warfighter encounters them in the course of a mission not originally directed at them. It should be no surprise that ATR systems will enter the inventory first for stationary target before moving targets. Even

with this being the case, mission planning will continue to be an area of constant trades between ATR needs and reconnaissance capabilities even for stationary targets.

In addition to finding ships at sea, armor targets represent a difficult target to mission plan as illustrated in Figure 14. There is a greater likelihood of a mix of friendly, civilian and enemy forces. Armor can be masked or hidden by trees, hills or buildings.

Although ships are normally always moving, armor can often be moving or stationary and rapidly change from one state to another. The functionality required for armor targets has more dimensions associated with it such as picking a lethal aimpoint or rejecting civilian or friendly vehicles.

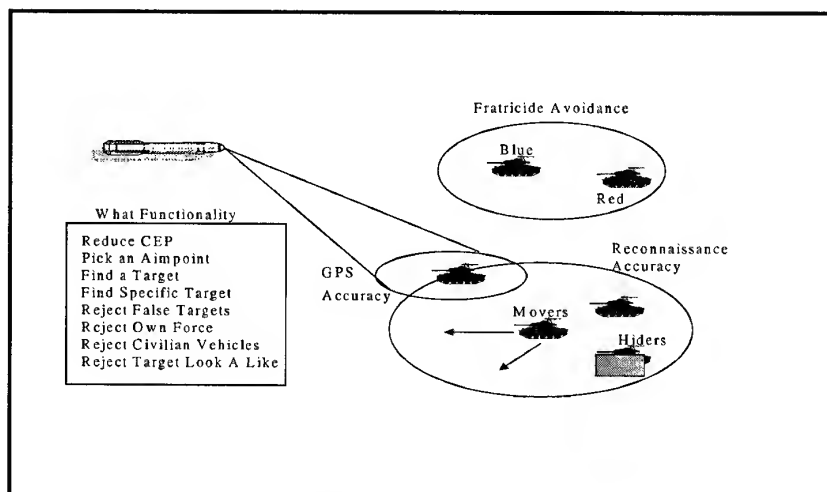

Figure 14 Armor Target

Figure 15 Variability in Armor Targets

One difficulty associated with recognizing armor targets that has increased with the end of the cold war is the numbers and types of armor. As figure 15 illustrates, they all have all have similar attributes (ie. treads, wheels, hatches, barrels, etc.) and it makes designing a target template difficult. If the distinguishing part of a target is masked and the common part is visible it can easily be assigned the wrong target type. A higher fidelity in processing is required for armor or the performance goals must be set lower than for large stationary targets.

Defining A Reasonable Set of ATR Requirements

Before a company can pursue building, marketing and selling an ATR product with or without a warranty, a reasonable set of ATR requirements must be selected as illustrated in Figure 16. Considering the ATR design space or mission space, the product must be

designed not for every mission or application but for a reasonable subset that a designer can satisfy and a systems engineer can define requirements that can be converted to acceptance tests. This requires the ATR developers to become focused on a narrow market and remain focused long enough to create a true product.

Not every mission area is ready for this product focus as illustrated in Table 1. Some mission areas such as finding camouflaged targets requires technological breakthroughs or near instantaneous reconnaissance data.

Trends in ATR Technology

As shown in Figure 17 there are many technology trends in the ATR area but probably the one with the greatest attention is multisensor ATR that requires fusing data from multiple sensor systems that potentially operate at very different wavelengths. The

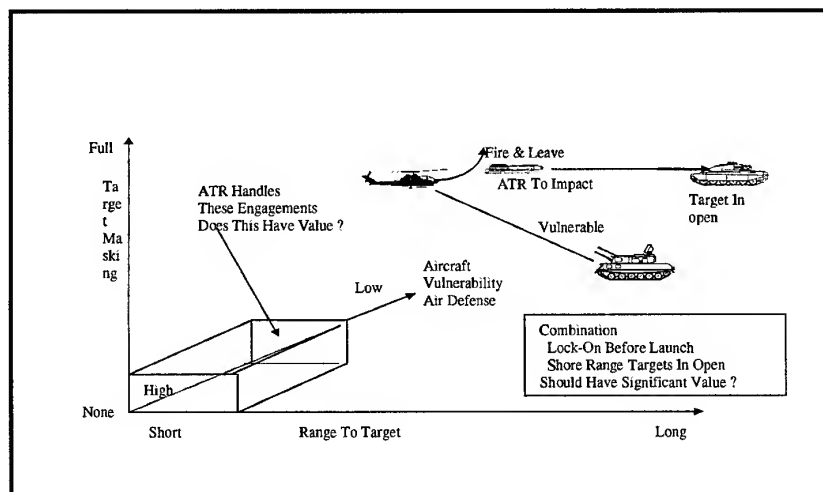

Figure 16 Bounding The ATR Requirements

Requirements & Targets		Fixed Target		Moving Or Relocatable	
		Large	Small	Not Obscured	Obscured
Good Weather	No Countermeasures	INS/GPS Has Made This Practical	Stress Weapon Maneuverability	Faster Processors & Timely Cueing	Fine Resolution Sensors
	Countermeasures GPS Jamming Sensor Jamming Deception High Probability Obscuration	Multisensor Fusion Systems	Requires Sensor Development And Higher Weapon Maneuverability	Requires Development Of Multisensor Fusion Systems	Multisensor Fusion Systems And Fine Resolution
Adverse Weather	Cloud Cover	Faster Processors	Faster Processors & Higher Resolution	Rapid ATR & Sensor Search	Rapid ATR & Sensor Search Plus Fine Resolution
	Worst Day Of The Battle	Sensors That Are Not Weather Limited	High Resolution Sensors Not Weather Limited	Sensors That Are Not Weather Limited	Fine Resolution Sensors That Are Not Weather Limited

Table 1 Mission Area Maturity

impact of GPS has already been felt in the ATR community but even tighter coupling between ATR and GPS can be expected in the future. Treating ATR as a systems problem is a new trend and the author hopes one that will gain even greater interest because it is this trend that will lead to more of a product focus. Trends in the area of artificial intelligence and other new processing approaches have decreased some and now fall more in the category of another tool available to the ATR designer.

Future Weapons Employing ATR

In the next millenium, ATR will reach the product phase and enter the military inventory. The most likely first significant introduction will be in the area of Strike Warfare for large fixed targets. This will especially become important in the long range destruction of an enemies air defense systems during the first few days of a military conflict. Although Synthetic Aperture Radar seekers are growing in maturity, ATR will be used first with the new generation of infrared seekers using high resolution, focal plane arrays. When cloud cover obscures the target, these weapons will rely on GPS to get to the target area and then acquire the target just beneath the

cloud cover. Missiles such as these will have a minimum useable cloud cover since the missile has a limited maneuverability. This may even create a need for airframes with higher maneuverability in the end game. Ballistic missile defense is another area where ATR will have some early success since targets are easier to find above the clouds and against a clear sky background. These systems will use infrared and millimeter wave seekers. The emphasis in these applications will be on recognizing a lethal aimpoint.

Deployment of anti-armor seekers using ATR will be restricted to targets in the open and this means dual mode seekers using laser acquisition for more stressful target scenarios. Because anti-armor missiles traditionally have small warheads, aimpoint determination will continue to be a key figure of merit for these systems. ATR guided weapons for use against relocatable missile launcher will be slower coming because of the greater difficulty of the problem and the need for synthetic aperture radar seekers and new types to missiles which fly at hypersonic speeds to reduce time-to-target.

Summary and Conclusions

It can be expected that the next millenium will be an exciting time for ATR systems as high speed video processors reach the commercial marketplace and video software development tools rapidly become common place. ATR technology can be expected to transition from technology to product. The first applications in the area of strike warfare against large fixed targets and air defense installations but anti-armor systems will follow shortly after. These first systems will encounter difficulties caused by the complexity of the ATR problem, lack of adequate user training and the growing unpredictability of the post cold war battlefield. The author believes that this process can be accelerated by more of an integrated seeker approach and the training of ATR seeker systems engineers who can define product requirements and key system design trades. ATR must move from a "Algorithm Centered World" to a "Product Centered World."

Abstract

This paper presents a review of Inertial Navigation Systems (INS) and the Global Positioning System (GPS) as a key technology for Strike Warfare beyond the Year 2000. The paper reviews the functionality that INS/GPS provides the Missile Guidance, Navigation and Control (GNC) designer plus the requirements associated with this functionality. Existing systems on the market are reviewed and new systems that can be expected to enter the market in the 2000 to 2010 time frame are discussed. System issues associated with the use of this hardware and trends in system integration methods are reviewed. The paper concludes with a discussion of the likely future uses of INS/GPS in precision strike missiles.

Applications of INS/GPS in Strike Warfare

Two primary uses of INS/GPS in Strike Warfare are low cost guidance tailkits for dumb bombs and midcourse guidance for long range precision strike missiles. Tailkits such as JDAM that include an integrated INS/GPS can be attached to dumb bombs and reduce the dispersion of the bombs to the inherent accuracy of the GPS system (15 Meter CEP). These inexpensive guidance kits which do not require a seeker provide a precision strike capability at a much lower cost than weapons requiring a terminal seeker. These INS/GPS guided weapon are only useful for a portion of the fixed targets of interest to Strike Warfare but they provide a very valuable operational capability.

INS/GPS also provides accurate midcourse guidance for long range standoff weapons attacking fixed targets. The INS/GPS midcourse guidance system can guide the weapon accurately enough that when the seeker turns on, the target will be within the field of view of the seeker. There is no need to scan the seeker back and forth to locate the target. The seeker turns on and expects to find the target within the current seeker field-of-view (FOV). After the seeker turns on, acquires and tracks the target, the INS/GPS tracks the target location between target updates. In the presence of cloud cover, INS/GPS guides the weapon through the clouds until the seeker has a clear view of the target. In this scenario, the INS/GPS is viewed as providing a through the clouds attack capability.

Engageable Threats

The target types that lend themselves to being attacked by INS/GPS guided weapons are primarily stationary targets. Fixed targets can be located and surveyed using reconnaissance assets. The coordinates of these fixed targets can be loaded into the weapon computer and the onboard INS/GPS can guide to the target coordinates.

Special types of fixed targets that cannot be easily surveyed prior to the mission can also be attacked with INS/GPS. An antiradiation missile can use INS/GPS to guide to the last computed target coordinate should the antiradiation seeker lose the target. This can provide an important operational capability to deal with the loss of a threat signal during the missile terminal guidance phase.

Moving or relocatable targets cannot be attacked with a weapon guided solely by INS/GPS. These targets require a seeker to correct for target location uncertainty. However, INS/GPS can help reduce the complexity of the relocatable target acquisition problem for the seeker of choice.

Response Time

Missile response time from power up to ready for launch can be impacted by the presence of an INS/GPS system. The inertial navigation system must go through an alignment process to find local level and north that can take several minutes. GPS must acquire the satellite signal and decode the signals that can take minutes to accomplish. An integrated INS/GPS can, therefore, become a limiting factor in missile response time.

Two distinct types of alignment scenarios exist for tactical missiles depending on the missile system approach taken to handling this requirement. The INS/GPS system can be aligned on the runway prior to the aircraft taking off. Alignment in this case is easier because the aircraft is stationary, but once aligned, power must remain on the weapon through the aircraft flight. The second approach is in-air alignment that requires aligning the weapon INS/GPS system to the aircraft INS/GPS system. This second approach assumes a modern digital interface to the weapon store location and many older aircraft lack this digital bus. Newer aircraft include a digital bus to the weapon and in-air alignment will grow in popularity in the future.

When performing in-air alignment, the accuracy of the alignment is enhanced by aircraft maneuvers during the alignment process but this approach is unpopular with pilots and could be totally unacceptable in the case of stealth aircraft. Ultimately the in-air alignment accuracy is limited by flexure of the aircraft structure between the aircraft INS/GPS and the weapon INS/GPS. Since GPS acts as a separate external alignment device for the INS, this structural flexure problem is more of a concern when using free inertial systems that do not include GPS.

Type of Inertial Products

Inertial products come in various configurations. At the lowest level are the inertial instruments that measure the actual missile motion. Angular motion is measured using a gyroscope whose digital output is a linear function of the rotation rate about its input axis. Each gyroscope measures one axis of rotation so three gyroscopes are required to measure the 3 dimensional rotation rate vector of the missile (pitch, yaw and roll). Translational motion is measured using accelerometers whose output is a linear function of the translational acceleration along its input axis. Three accelerometers are required to measure the 3 dimensional acceleration vector of the missile. Older missiles used gyroscopes and/or accelerometers in the missile autopilot to maintain stable missile flight characteristics. Gyroscopes were also used to stabilize the seeker optics or antenna. Figure 1 illustrates the difference between an IMU (Figure 1a) that is a cluster of 3 gyroscopes and 3 accelerometers required to measure the complete missile rotation and acceleration vectors and an INS (Figure 1b) that computes location on the earth using IMU outputs. A missile can use an IMU for autopilot functions and seeker stabilization without adding the computer necessary to compute location on the earth. The trend is towards integrated INS/GPS systems. GPS requires a complete navigation system to maintain synchronization with the satellite signals

and the INS needs GPS to keep the navigation error from growing without bound as illustrated in Figure 1b.

Types of INS Systems

Figure 2 shows pictures of a typical aircraft integrated INS/GPS system and a typical tactical missile INS. There is obviously a significant size difference. The aircraft INS has a larger IMU and this translates into more accurate inertial sensors. The aircraft INS must provide significantly more functionality since an aircraft has many missions and mission packages with a complex set of INS requirements. The aircraft INS holds more electronic circuit cards and often uses temperature stabilization for the inertial measurement cluster. In contrast with the aircraft INS, the missile INS is more limited in its functionality and scope. It uses smaller sensor and smaller electronics. The loss of navigation accuracy with time in the absence of GPS is an order of magnitude higher in the tactical missile INS than the aircraft INS. Since the INS includes an IMU a tactical missile INS can provide the signals required by the missile autopilot, the seeker optics/antenna stabilization, midcourse navigation and terminal guidance requirements.

One trend in tactical missiles that will help reduce the size and cost of tactical INS is to avoid redundant hardware and software through a system architecture that emphasizes a high degree of system integration. Modern missiles will use one central power supply or one central processor eliminating the need for the INS to have a separate power supply or processor.

Example of Current Inertial Products

Figure 3 shows several pictures of inertial products found at various websites on the internet. Many systems use laser gyroscopes that were developed over a 20 year time frame. The laser gyroscope on the left

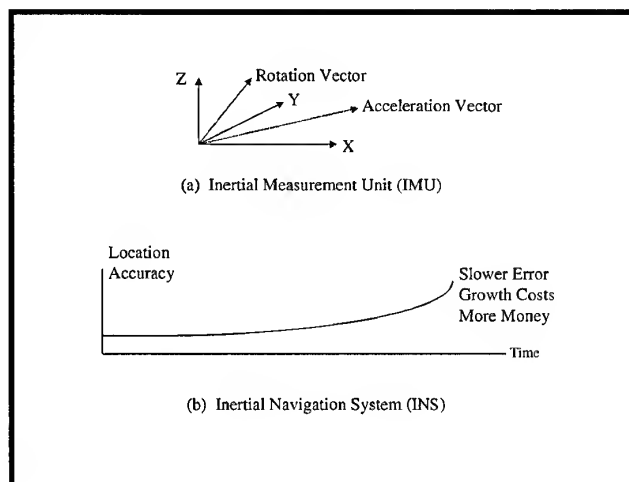

Figure 1. IMU versus INS

(a) Aircraft Grade INS

(b) Tactical Grade INS

Figure 2. Size Variation in INS Systems

Figure 3. Sampling of Inertial Products

of figure 3 is the world largest and helps give a better view of the gyroscopes structure. A laser gyroscope uses two counter rotating laser beams that interfere with each other when they meet at one corner of the cube. The degree in interference is a function of the rotation rate about an axis normal to the laser gyroscope. A smaller tactical missile grade laser gyroscope is also shown in figure 3. Figure 3 also shows a more traditional spun rotor gyroscope using a rotating mass driven by a motor. Accelerometers are still primarily the force balance or mass on a spring design. A triad of accelerometers is shown on the bottom right of figure 3. Figure 3 includes one example of an inertial cluster including three orthogonal gyroscopes and three orthogonal accelerometers.

Trends in Inertial Sensors

There are new types of inertial sensors being developed that are expected to enter the market place in the next 5 - 10 years. This includes a fiber optic gyroscope similar to a laser gyroscope but capable of achieving a longer path length by using a spool of fiber optic cable. A fiber optic gyroscope can achieve the same sensitivity as a laser gyroscope but in a much smaller package. A newer technology that has significant commercial market potential is the Micro-Electro-Mechanical Systems (MEMS). MEMS is the integration of mechanical elements, sensors, actuators, and electronics on a common silicon substrate through the utilization of microfabrication technology. These MEMS sensors can be packaged in very small sizes and have the potential for high rate/low cost production. A key factor in the ability of tactical INS manufacturers to build lower cost products will depend on the success of MEMS technology and the development of a commercial market for inertial sensors.

Initially the newer inertial sensors will lack the accuracy of the older sensor designs, but since GPS can work with lower accuracy inertial systems, this will not limit the introduction of these new sensors. As the manufacturing processes for these newer sensors mature, they will reach and perhaps surpass the performance of the current inertial sensors.

Missile Guidance Functionality Impacted by INS Performance

An INS can support many different parts of an integrated missile guidance, navigation and control (GNC) design. This includes:

- source of autopilot measurements of missile short term motion
 - missile rotational rate about the weapon center of gravity and acceleration through the weapon center of pressure

- source of midcourse guidance information on missile location relative to the expected target location
- source of seeker measurements of missile motion required to support
 - sensor compensation
 - imaging sensor
 - image motion stabilization
 - radar
 - range and/or velocity to scene center
 - synthetic aperture radar - image formation
 - short term missile motion
 - sensor cueing
 - point where the target is expected to be - sets search area
 - ATR cueing
 - fixed target approach angles plus range to target
 - multisensor fusion
 - change in missile aspect between different sensor collection times
 - source of guidance commands between sensor updates
 - guides after sensor goes blind

All these GNC functions have different requirements that must be integrated into the total design requirement for the integrated INS/GPS. Balancing these different design requirements without growth in the cost of the INS/GPS system is a very challenging design problem.

Missile INS Need Statement

A missile needs an INS/GPS primarily to guide the missile to the target area when the launch range is beyond lock-on before launch ranges or the missile does not contain a seeker. The missile also needs an INS/GPS system to keep the missile seeker pointed at the target during missile maneuvers. As already mentioned to guide a weapon over long ranges with a tactical grade INS would require a very expensive INS with low drift rate or GPS as a navigation update device. Many new sensors also have short acquisition range so there isn't much time for the seeker to scan around and search for the target. An accurate INS/GPS system can often guide the missile to the target to sufficient accuracy that the target will be in the sensor field-of-view at sensor turn-on.

A secondary missile need for an INS in the case of fixed targets is providing the automatic target recognition (ATR) system information on the target viewing angles and range to the target at sensor turn-on. This information significantly reduces the complexity of the ATR problem for fixed targets. This need for an INS/GPS to reduce ATR complexity is not as well understood by missile designers today nor is it understood how to exploit INS/GPS to reduce

the complexity of the moving or relocatable target ATR problem.

Missile Performance Metrics Impacted by INS/GPS Performance Metrics

The performance of the integrated INS/GPS system impacts several important missile level performance metrics. The most obvious metric that is impacted is the missile circular error probability (CEP). This is especially the case for missiles that are totally guided using an INS/GPS. In the case of INS/GPS guidance the CEP is limited by a combination of GPS accuracy and target location accuracy. Normally the CEP of an INS/GPS guided weapon is on the order of 15 meters.

INS/GPS performance also impacts the maximum weapon range. This is especially the case when GPS is not used and midcourse guidance is free inertial. In the case of INS/GPS the impact is only seen if the missile operational scenario includes a GPS jammer in the target area. GPS has made it easier to fly longer midcourse navigation ranges prior to seeker turn-on.

INS/GPS can provide a degree of adverse weather performance. INS/GPS weapons can attack fixed targets through the clouds. Laser guided weapons or optical guided weapon cannot penetrate cloud cover and must acquire the target after penetrating the cloud cover. INS/GPS also helps to hold the missile on the

target when the seeker line of sight to the target is interrupted for any reason or the seeker temporarily locks onto a false target.

INS/GPS performance impacts the type of target that can be attacked. Fixed targets are very compatible with INS/GPS guidance. Relocatable or moving targets require a seeker but INS/GPS can reduce the seeker search area. Therefore, the INS/GPS performance will impact the performance of the missile across the total mission target set.

INS/GPS performance impacts warhead effectiveness. The INS/GPS makes it easier to achieve the terminal impact condition required for maximum warhead effectiveness. This includes the impact angle and angle of attack of the missile at target impact.

INS Error Model

Figure 4 shows a simple error model for the INS system. Since the inertial measurement devices measure rotational rate and translational acceleration, the computer in the INS must integrate these measurements to obtain missile attitude, translation velocity and position. The block diagram shown in figure 4 is made up of several integrators. The errors associated with the different inertial sensors pass through a different number of integrators. The more integrators the errors pass through, the faster the

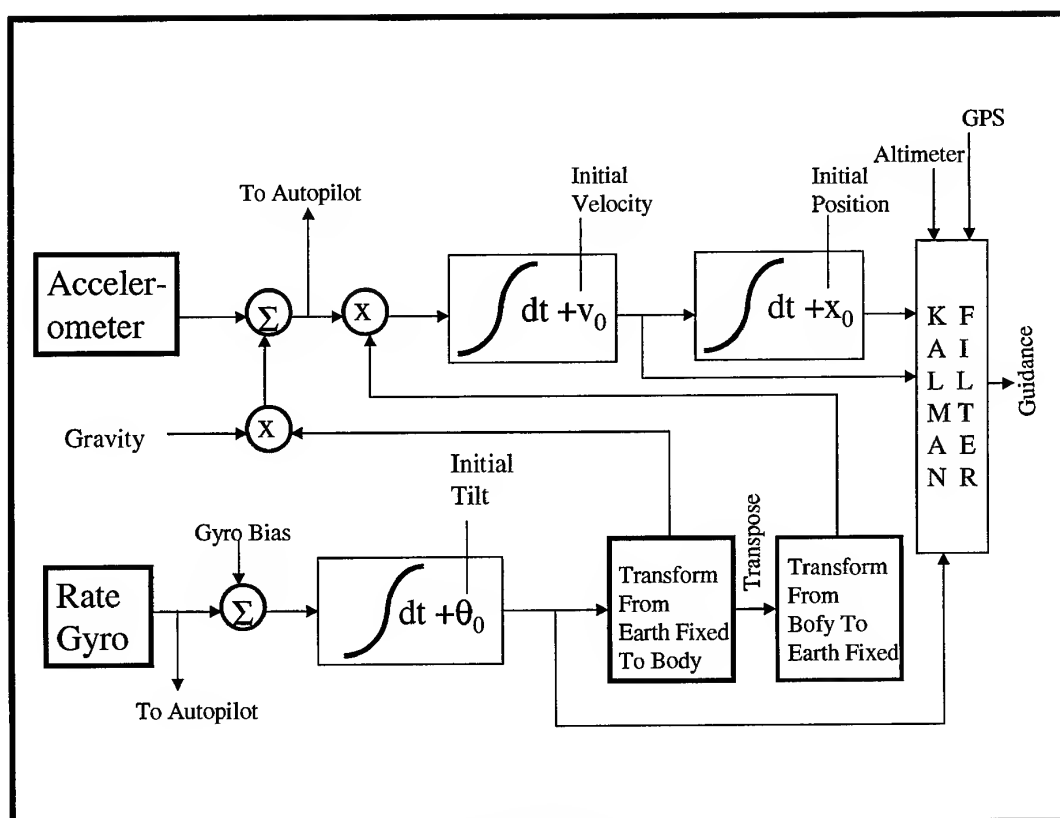

Figure 4. INS Error Model

associated position error grows with time. For example, gyro bias is integrated to create a tilt error that multiplies gravity to create an acceleration bias. The acceleration bias associated with the gyro bias induced tilt error is double integrated to create a position error that grows with the third power of time. The velocity bias error only passes through one integrate and grows with the first power of time.

It is possible to misinterpret these different errors and their impact on position error as a function of time. For short time of flights, the velocity bias dominates even though it grows only linearly with time. Gyro drift dominates for long times of flight since it grows with the cube of time. One reason is that velocity bias is usually larger than the acceleration bias and it is usually larger than the gyro bias.

All the INS errors can in general be approximated as an error of the form kt^n where k is a constant including the error term, t is time and n is the power 0, 1, 2 or 3. These simple error models are very compatible with computing INS errors using a handheld calculator or a spreadsheet. Computing the errors when GPS is used to update the INS is even simpler since the position and velocity errors are fixed by GPS in the steady state and that is normally the phase of interest to the missile designer.

Figure 5 shows the position error growth as a function of time caused by acceleration bias and gyro drift starting from a perfect alignment. Note that for the short term, there is little difference between these INS units. In the long term, the curves diverge

considerably because of the difference in gyro drift rates. This long term drift is only important for missile designs that do not include GPS or in the case of GPS jamming.

Missile Motion and INS Performance

So far, all the discussions about the INS/GPS system has dealt with very low frequency motion which can be represented by powers of time. Navigation systems traditionally are concerned with low frequency motion measurement as illustrated in figure 6. Imaging sensors such as synthetic aperture require the measurement of motion frequencies higher than frequencies traditionally of interest to navigation designers. These sensors need an accurate measurement of short term motion and even requires measurement of missile vibration that might be induced by the propulsion system or actuator motion. As figure 6 illustrated, vibration can extend far beyond traditional motion frequencies. Accurately measuring this high frequency motion is a new requirement for INS designers and not yet fully understood by many.

As figure 7 illustrates, measuring the higher frequency motion of a missile requires a higher sampling rate and falls more into the area of expertise of the digital signal processing designer than the navigation designer. This high frequency motion measurement must concern itself with small changes in position on the order of a radar wavelength. A need exists to balance the INS design between the needs of the midcourse navigation system and the imaging seeker needs.

Figure 5. Representative Tactical Grade INS Position Growths

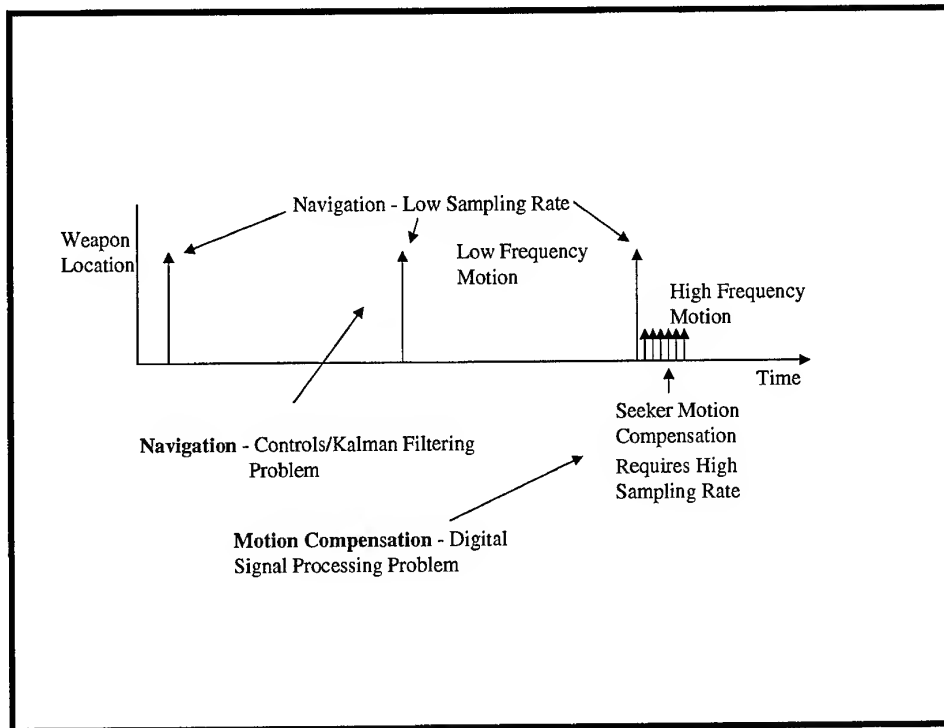

Figure 6. Motion Signal Processing Design

Figure 7. Missile Motion Bandwidth and INS Function

Figure 8. Sampling of New or Proposed Tactical Grade INS Systems

New Tactical Grade INS Systems

Figure 8 shows a sample of new or proposed tactical grade INS units based on emerging technologies. Perhaps only one of these new units will reach high rate production. These units will probably not fill all the needs of future tactical missiles. The missile GNC designer will have to develop design architectures that fit these new INS units at costs consistent with new procurement guidelines. There will be many challenging design problems but these products will help reduce the cost of future tactical missiles.

Integrated INS/GPS Cost

Since cost is very important in the current military acquisition approach for tactical missiles, it is necessary to point out that cost includes not only the selling price but also the warranty cost and repair cost. It is not unusual today for the military to require a warranty on new missile and require the supplier to maintain and repair the weapon. Inertial products developed for the commercial market place may not be compatible with a 10, 15 or 20 year warranty. Validating a warranty may take a sizeable investment

and require some redesign of units currently under development.

Tied to cost is risk management. There are many risks associated with phasing a new INS into a production missile. The trend is to go with an INS that is already in production so new INS system will first be introduced for those applications that have strong needs such as small package sizes below those currently produced.

Summary and Conclusion

In summary, integrated INS/GPS systems are a key technology for tactical missiles and will provide increasing levels of functionality as missiles include advanced imaging seekers and seekers incorporate automatic target recognition. This trend towards increased use of integrated INS/GPS systems is supported by the development of small tactical grade INS units using MEMS and fiber optic technology. INS designers have to increase their understanding of new INS requirement created by imaging infrared and radar sensors.

14. Abstract	<p>This lecture series addressed recent advances in the state-of-the-art for precision strike missile systems. Emerging technologies that were addressed in the lecture series included:</p> <ul style="list-style-type: none"> • <i>Missile aeromechanics technologies.</i> Assessments included hypersonic airframes, low cost/high temperature structure, and ramjet propulsion. • <i>Guidance & control technologies.</i> An overview of existing guidance and control was given. Assessments included precision navigation using light weight/low GPS/INS and optimal guidance laws. • <i>Seeker technologies.</i> Assessments included active and passive imaging infrared and radar seekers. • <i>Missile design technologies.</i> Assessments included computer programs and electronic spreadsheets for conceptual design. • <i>Missile/aircraft integration technologies.</i> Assessments included high firepower weapon concepts, reduced observables, and insensitive munitions. • <i>Simulation/validation technologies.</i> Assessments included hardware-in-the-loop and design validation. • <i>Automatic target recognition.</i> Assessments included robust algorithms and hardware/algorithm optimization.

DIFFUSION DES PUBLICATIONS

RTO NON CLASSIFIEES

L'Organisation pour la recherche et la technologie de l'OTAN (RTO), détient un stock limité de certaines de ses publications récentes, ainsi que de celles de l'ancien AGARD (Groupe consultatif pour la recherche et les réalisations aérospatiales de l'OTAN). Celles-ci pourront éventuellement être obtenues sous forme de copie papier. Pour de plus amples renseignements concernant l'achat de ces ouvrages, adressez-vous par lettre ou par télécopie à l'adresse indiquée ci-dessus. Veuillez ne pas téléphoner.

Des exemplaires supplémentaires peuvent parfois être obtenus auprès des centres nationaux de distribution indiqués ci-dessous. Si vous souhaitez recevoir toutes les publications de la RTO, ou simplement celles qui concernent certains Panels, vous pouvez demander d'être inclus sur la liste d'envoi de l'un de ces centres.

Les publications de la RTO et de l'AGARD sont en vente auprès des agences de vente indiquées ci-dessous, sous forme de photocopie ou de microfiche. Certains originaux peuvent également être obtenus auprès de CASI.

DISTRIBUTION OF UNCLASSIFIED

RTO PUBLICATIONS

NATO's Research and Technology Organization (RTO) holds limited quantities of some of its recent publications and those of the former AGARD (Advisory Group for Aerospace Research & Development of NATO), and these may be available for purchase in hard copy form. For more information, write or send a telefax to the address given above. **Please do not telephone.**

Further copies are sometimes available from the National Distribution Centres listed below. If you wish to receive all RTO publications, or just those relating to one or more specific RTO Panels, they may be willing to include you (or your organisation) in their distribution.

RTO and AGARD publications may be purchased from the Sales Agencies listed below, in photocopy or microfiche form. Original copies of some publications may be available from CASI.
